20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

Miller Sands, an island-lagoon complex located in the Columbia River Estuary at River Kilometre 39 (River Mile 24) was one of five research projects where the feasibility of using dredged material for beneficial habitat development was studied. The study was conducted during predisposal, disposal, and postdisposal phases from March 1975 to July 1977. The National Marine Fisheries Service was part of a five-agency team charged with the investigation

20. ABSTRACT (Continued).

of various physical, chemical, and biological parameters during the marsh development program. The National Marine Fisheries Service research findings describe changes in sediments, macroinvertebrates, various water quality parameters, zooplankton, nekton, and nekton food utilization.

Twenty species of finfish totaling 13,755 organisms were captured with beach seines and fyke nets during the day and night at 13 different sites during the study. Four species dominated the catch during fifteen bimonthly surveys and accounted for 93 percent of the total catch i.e. juvenile chinook salmon, peamouth chub, starry flounder, and threespine stickleback. A change occurred in fish abundance during the postoperational phase, but this change was attributed to behavioral reactions by anadromous and nonanadromous fish to a 100-year record low-flow condition experienced in the Columbia River during the winter, spring, and summer of 1977. Statistical analysis of age, weight, length, and abundance of nekton captured failed to reveal any significant changes as a result of disposal or as a benefit of habitat development at Miller Sands.

Over 54,000 prey organisms representing 36 taxa were consumed by nekton sampled during food utilization studies at Miller Sands. Four main species of prey items made up 95 percent of the total numbers of items consumed by all fish at all sampling stations. These were Daphnia, Eurytemora, Corophium, and chironomid larvae and pupae. The sizes of fish did not significantly affect the food habits of most fish. While the large fish were able to consume greater quantities of food, the species composition was similar for all sizes. There were few differences between day and night samples, between cove and intertidal areas, and among stations within the cove area. With few exceptions, nekton species contained food during the entire study and were feeding in the Miller Sands area.

Results of sediment analysis indicated that sediment size and types were fairly uniform throughout the area. Fine sand and silty sand comprised the main sediment types at all stations. Organic matter was between 3 and 8 percent and there was no significant seasonal change. The average number of benthic organisms per square metre was highest the first year, and declined monotonically to the end of the study. A clam, an amphipod, a flatworm, and an important mysid (Neomysis) were not found in 1976-1977. Oligochaetes, Corophium, and chironomids constituted from 92-94 percent of the total organisms captured at Miller Sands. Over 209,000 benthic organisms representing 22 taxa were captured during the study.

Zooplankton were dominated by two Cladocerans, Daphnia and Bosmina, and one copepod, Cyclops. These three organisms represented 96 percent of the zooplankton collected and were present at all sampling stations during the first year of the study. However, sampling of zooplankton was excluded from the postoperational surveys.

Water flow conditions in the Columbia River were high in 1975, average in 1976, and were exceedingly low during the winter of 1976 and the spring-summer of 1977. Water quality parameters that were manifested as a result of these changes in flow probably overpowered subtle changes that could have developed as a result of the habitat improvement project at Miller Sands. Water quality parameters monitored were water temperature, pH, salinity, dissolved oxygen, turbidity, ammonia, total alkalinity, and nitrogen gas.

PREFACE

The work described in this report was performed under Interagency Agreement Numbers WESRF 75-88, WESRF 76-39, and WESRF 76-178, between the U. S. Army Engineer Waterways Experiment Station (WES), Vicksburg, Mississippi, and the National Marine Fisheries Service (NMFS), Prescott, Oregon. The research was sponsored by the Office, Chief of Engineers, U. S. Army, under the Dredged Material Research Program (DMRP). The study, which was part of the Habitat Development Research Program was conducted in the lower Columbia River at Miller Sands during the period May 1975 through July 1977.

We would like to express our appreciation to Mr. George Snyder, Assistant Director, Field Research Programs, NMFS, Seattle; and Mr. Theodore Blahm, Station Chief, Prescott Field Station; and to the following members of the Prescott and Hammond Station staffs: Larry Davis for the collection and analysis of water chemistry, and collection of benthic organisms; Maurice Laird and Edward Koller for collection of nekton; Suzie Valder and John McNair for the sorting and identification of benthic organisms; Nancy Knox and Mary Lee Brown for preparation of graphics, compilation of data, and overall report preparation; Norm Kujala for analysis of the 1975-1976 benthic data; and Linda Jennings and Tracy Brown for help in recording and tabulation.

The report was prepared for the Habitat Development Project (HDP), (Dr. Hanley K. Smith, Manager) as part of Task 4B: Terrestrial Habitat Development. Specific Sub-Tasks assigned to the NMFS included 4B05C, Baseline Biological Inventory and Assessment of the Aquatic Environs of the Miller Sands Habitat Development Site; 4B05J, Aquatic Biology Investigations at Miller Sands Habitat Development Site, Columbia River, Oregon, and 4B05L, Post Operational Aquatic Biology at Miller Sands Habitat Development Site. The contracts were managed by Dr. Dave Parsons, Dr. John Bryne and Mr. Ellis J. Clairain, under the general supervision of Dr. John Harrison, Chief, Environmental Laboratory. Mr. John D. Lunz prepared the Scope of Work for the project in March 1976.

COL. G. H. Hilt, CE, and COL. J. L. Cannon, CE, were Directors of the WES during the conduct of this study, and Mr. F. R. Brown was Technical Director.

TABLE OF CONTENTS

HABITAT DEVELOPMENT FIELD INVESTIGATIONS, MILLER SANDS MARSH AND UPLAND HABITAT DEVELOPMENT SITE, COLUMBIA RIVER, OREGON

APPENDIX B: INVENTORY AND ASSESSMENT OF PREDISPOSAL AND POSTDISPOSAL AQUATIC HABITATS

PART I: INTRODUCTION

Background

1. Miller Sands, an island-lagoon complex located in the lower Columbia River, is one of five research projects where the feasibility of using dredged material for beneficial habitat development is being studied. The objective of these studies is to provide information on the environmental impact of dredging and dredged material disposal and to develop economically feasible dredging and disposal alternatives which are environmentally compatible.

2. The U.S. Army Corps of Engineers (CE) Environmental Laboratory (EL) of the Waterways Experiment Station (WES) at Vicksburg, Mississippi has the overall responsibility for the Habitat Development Research Project (HDRP) at Miller Sands.

3. Principal investigators at the Miller Sands project were Portland District Corps of Engineers, Oregon State University, Washington University, Wave Beach Grass Nursery, and the National Marine Fisheries Service.

4. In 1975 the Environmental Conservation Division, National Marine

Fisheries Service (NMFS) contracted with the WES to provide a baseline biological inventory of the aquatic biota at Miller Sands. The baseline inventory encompasses two phases of the study, (1) preoperational phase: March, May and early July of 1975. (2) Operational phase: August 1975 through May 1976 during which time the recently deposited material was graded to provide for marsh development within the intertidal zone at the upper end of the lagoon. During the spring of 1976 National Marine Fisheries again contracted with WES to perform the research for the postoperational phase of the Miller Sands Habitat and Marsh Development Project, (July 1976-July 1977).

Site Description

5. Miller Sands is a horseshoe shaped island located approximately 39 kilometers (24 miles) from the mouth of the Columbia River (Figure B1). This large, dredged material, island marsh complex of approximately 96 hectare (240 acres) is part of the Lewis and Clark National Wildlife Refuge.

6. The main vegetated island was formed during the 1930's from sediments dredged from the navigation channel of the Columbia River. A 101 hectare (250 acre) cove was created during the 1950's by placing dredged material partially parallel and almost connecting with the main island at the upriver end. This sand spit has remained unstable and unvegetated. The results of these events formed the horseshoe shaped island-lagoon-sand spit complex that we find today (Figure B2).

7. The variable freshwater discharge of the Columbia River basin

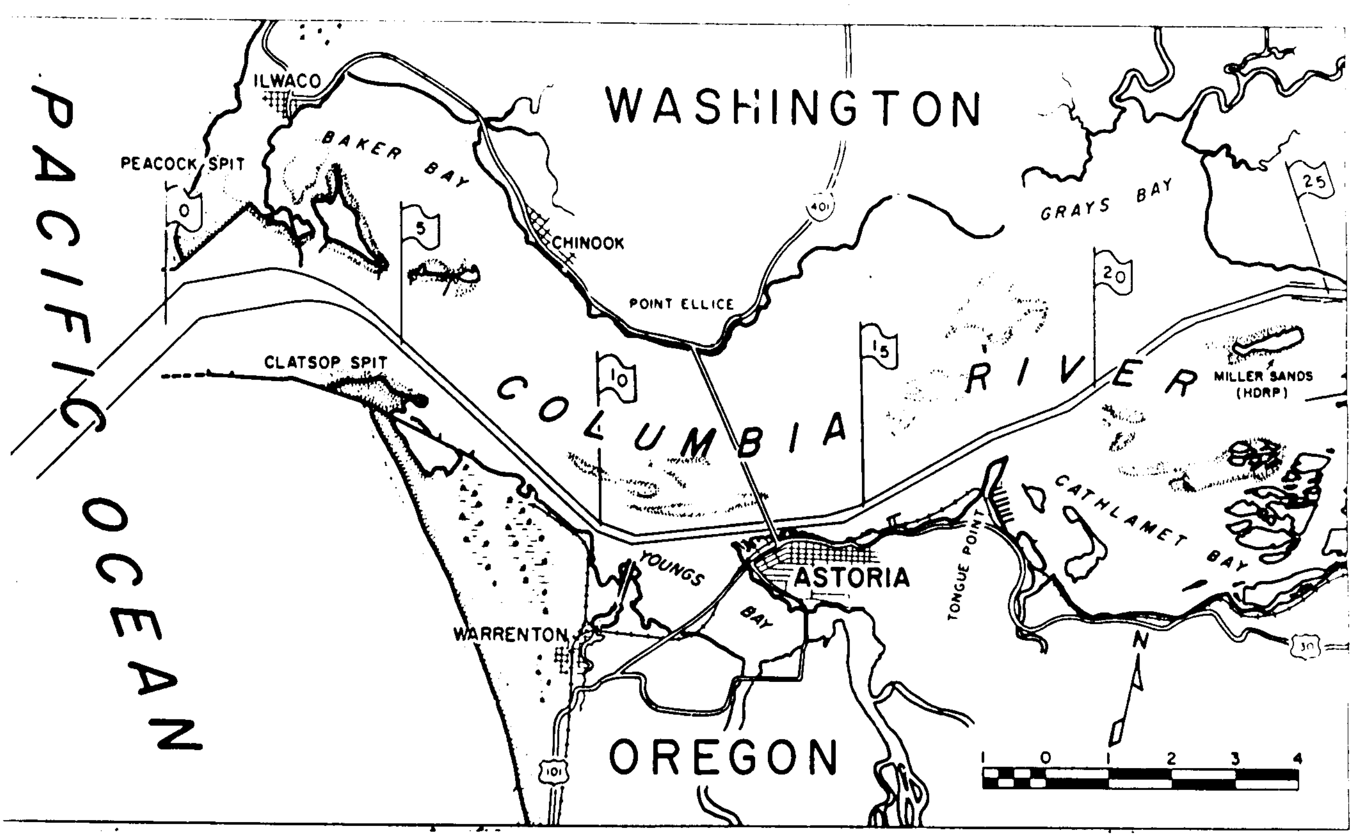

Figure B1. Location of the Miller Sands Marsh Development Site in Relation to the Columbia River Estuary.

combined with large tidal variations strongly influences the aquatic ecology of Miller Sands.

8. Freshwater discharge into the estuary is characterized by peak flows generally occurring during late spring (May-June), then decreasing to a low flow from August to October. Variable winter floods (December-January) may cause periods of high river flows which exceed the spring maximum.

9. Mean annual discharge for the fifteen year period 1961-1975 was 7,603 cubic meters per second (cms). During the 29 month study period at Miller Sands flows ranged from a monthly average high of 18,856 cms in May 1976 to a low of 2,432 cms in January 1977; these flows were 137% and 34% of their respective 15 year monthly averages.

10. Tidal variations at Miller Sands are of the mixed semidiurnal type characteristic of the Pacific Coast. Normally, the two high and two low tides are of unequal duration and height (average tidal cycle is 12 hours, 25 minutes). The mean tidal range from lower low water to higher high water is 2.59 meters (8.5 ft.) with extreme ranges approaching 3.6 meters (12 ft.).

11. Salinity intrusion, the distance saline water intrudes upstream, is constantly changing depending on tidal stage, fresh water runoff, and weather conditions. Maximum salinity intrusion occurs during high tide low runoff periods in the late fall. In October 1977, salinity of 8 ppt was measured at the bottom of the ship channel at river kilometer 42 (river mile 26). Minimum intrusion occurs with low tides and high river flow and may be less than 8 kilometers (5 miles), (Neal, 1965).

Figure B2. Photograph of Miller Sands showing the Cove, Island Complex and Development Site Adjacent to the Navigation Channel of the Columbia River.

12. The Columbia River estuary, because of its volume of freshwater discharge and large tidal variation, is extremely well-flushed. Neal (1965) calculated flushing time to be between 5 and 10 days. The cove at Miller Sands is also well flushed due to the channel at the upstream end of the island and the open end of the horseshoe downstream (Figure 2).

13. Water quality in the lower Columbia River and at Miller Sands is good compared with other large river systems in the United States. Dissolved chemicals generally have values less than the concentration standards set by Oregon's Department of Environmental Quality. Water quality problems do exist and are mainly associated with water temperatures during the late summer and fall, turbidity and dissolved atmospheric gases (nitrogen) during periods of high freshwater flow.

14. One of the major problems in the Columbia River Estuary is the continuing loss of productive aquatic habitat through dredge disposal and industrial or commercial land fills.

15. Two broad classes of sediments, organic and inorganic, form the substrate of an aquatic ecosystem. Inorganic sediments, sand, silt, and clay, are the major components of the sediments in the Columbia River, and are introduced into the estuary from the ocean, from river runoff or from local tributaries. Organic material which consists of dead plant and animal matter, chemical and industrial waste form a small fraction of estuarine sediments.

16. Substrate material collected and analyzed by the U. S. Geological Survey (Hubbell and Glenn, 1972) show an "average" sediment sample

from the estuary contains 15% gravel, 84% sand, 13% silt and 2% clay. This is a generalization and sediment texture varies widely throughout the estuary.

17. Water velocity and particle size are the important factors which determine if and how a sediment particle will be transported or deposited. Sand generally moves along the bottom with the flow of current while the fine material (silt and clay) remains suspended until water flow is reduced over shallow flats or stopped by tidal action.

18. The texture of a substrate is a controlling factor which determines the biological community which may be found at a given location. Sediments found in the channels and deep water areas are generally coarse (gravel and sand) and of little biological significance. Fine sediments (silt and clay) tend to settle out over low energy flat areas of the estuary and generally support an abundance and diversity of plant and animal life.

19. The tidally influenced, primarily freshwater, 101 hectare (250 acre) lagoon at Miller Sands is a protected, potentially productive aquatic animal habitat. Miller Sands and the shallow lagoon were formed from sand, dredged from the nearby navigation channel of the Columbia River. Theoretically, with reduced flows and the establishment of marshland vegetation in the lagoon, fine sediments (silt, clay) should settle out, changing the character of the substrate and increasing fertility.

20. Located at the upstream end of the Columbia River estuary, Miller Sands is rarely subjected to salinity intrusion, therefore the

planktonic and benthic invertebrates found in this area are limnetic (Haertel and Osterberg, 1966) (Misitano, 1974). These invertebrate organisms provide an important food source for the freshwater and brackish water fish species of the Columbia River estuary.

21. Chinook salmon (*Oncorhynchus tshawytscha*) are the most economically important fish originating in the Columbia River. This anadromous species provides a multi-million dollar income annually to fishermen in the Pacific Northwest. Juvenile chinook generally migrate during the spring of their first (fall chinook) or second (spring chinook) year of life. Numbers of fall chinook remain and feed in the lower Columbia River until the spring following their initial migration (Durkin and McConnell, 1973) (McConnell and Blahm, 1974).

22. Migration routes for all adult and juvenile anadromous fish are in close proximity to Miller Sands. These species include Chinook, Coho, Sockeye and Chum salmon, Steelhead trout, Eulachon, American Shad, and the largest of the freshwater fishes found in the Columbia River, the White Sturgeon.

Study Site Development

23. Miller Sands was originally constructed in 1932 from material dredged from the navigation channel of the Columbia River. In the early 1970's dredge material was deposited parallel to and almost connecting with the main island at the upstream end. This created a protected intertidal lagoon between the main island and the sand spit (Figure B3). Development of the marsh habitat at the upper end of the cove consisted

A. May 1975

B. April 1976

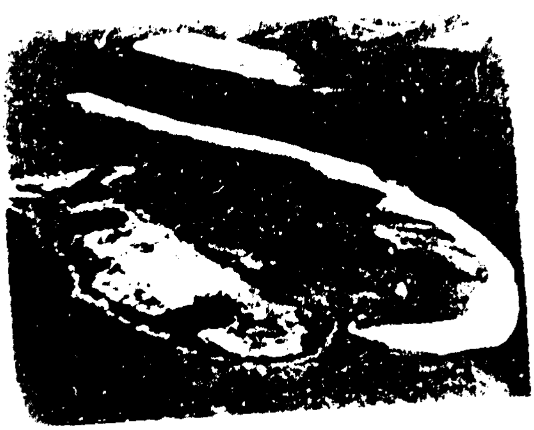

Figure B3. Photographs of Miller Sands During Various Pha
of the Habitat Improvement Project.

of grading material from the sandspit into a smooth sloping surface which covers approximately 4 hectares. This site was divided into 270 plots (10 by 14m) and during the spring and summer of 1976 these plots were planted in a factiorial design to test various species of marsh plants and fertilizer treatments; at three elevations within the intertidal zones.

24. Studies of the aquatic biota associated with Miller Sands were initiated in March, 1975. Three surveys, March, May and July, were conducted prior to the disposal operation in mid-July (Blahm 1975). These combined with six additional bimonthly surveys (August, 1975 to May, 1976) established a baseline inventory of existing aquatic biota near or in the cove at the Miller Sands complex. Baseline date collected during this pre-operational phase included nekton, zooplankton, and benthos. Water quality parameters were also monitored during the nine sampling periods.

25. In July, 1976 studies designed to assess the impact of dredge disposal and subsequent marsh development on the aquatic ecosystem at the Miller Sands site were initiated. The emphases of the six post-operational surveys (July 1976 to July 1977) was to document changes occuring in the macrobenthic and nektonic faunal communities associated with the cove. Biological data collected during this phase of the study included nekton at twelve stations and macrobenthic organisms at twenty-six locations throughout the cove at the Miller Sands site. Substrate materia. and water-quality parameters were monitored to determine if changes in the physical and chemical characteristics of the cove were occurring.

PART II: METHODS AND MATERIALS

Pre-Disposal Inventory

26. Samples were collected at seven stations in or near the Miller Sands complex during nine sampling periods March, May, July, August, September, and November 1975; and January, March and May 1976.

27. Station designations originally used by Blahm (1975) have been changed to correspond to site designations (Figure B4) used by the site manager from WES in the draft scope of work (March 10, 1976). Sample sites 2, 3, 5, 10 and 11 were located within the Miller Sands cove. Station 12 was located outside the lagoon, at the upstream end of the complex between the sand spit and navigation channel. The station at Snag Island (S.I.) was selected as a control site remote from Miller Sands. This site was discontinued in July 1976.

Post-Operational Studies

28. Eleven sampling stations, laid out in a grid pattern, were established in the cove at Miller Sands prior to the start of post-operational surveys. Cove stations along with Station 12 (previously described) are designated by numbers 1 through 12 (Figure B5).

29. Fifteen sampling stations were established along five transects in or near the intertidal, marsh experimental site. Sampling stations were located on each transect at the .3, 1.2, and 1.8 metre (1, 4 and 6 foot) contour elevations. Stations in the intertidal area are designated by transect (A through E) and site (1, 2 and 3). For example, C2 is the third transect from the main island and is on the 1.2 metre (4 foot) elevation.

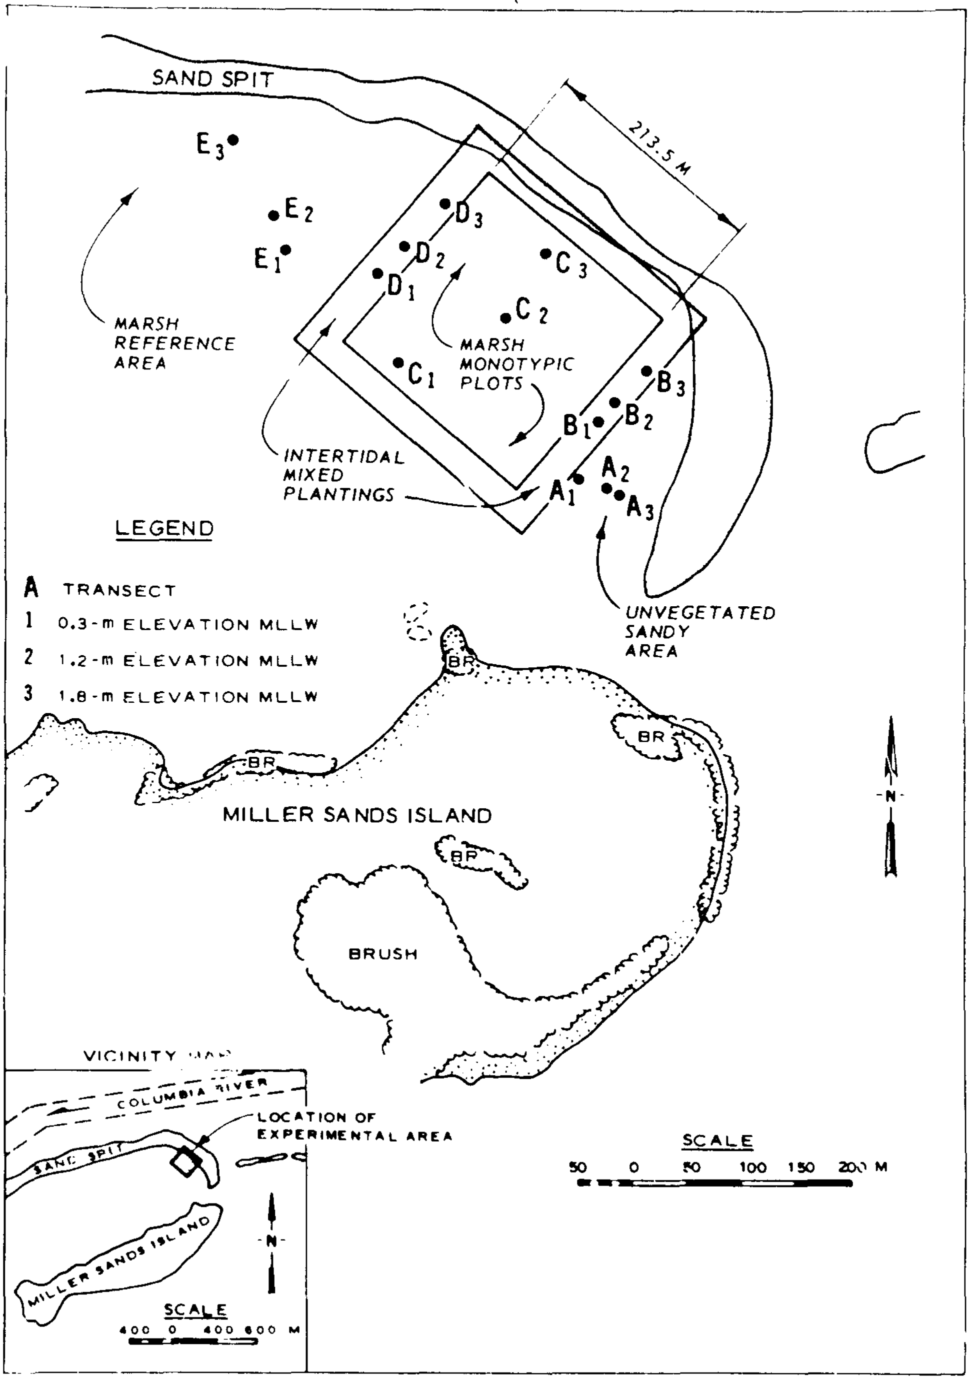

Figure 4. Field Location and Placement of Macrobenthos, Nekton and Water Quality Stations in the Intertidal Area of the Miller Sands Site, Columbia River, Oregon. Each Station is Located in Relation to a Specific Intertidal Elevation.

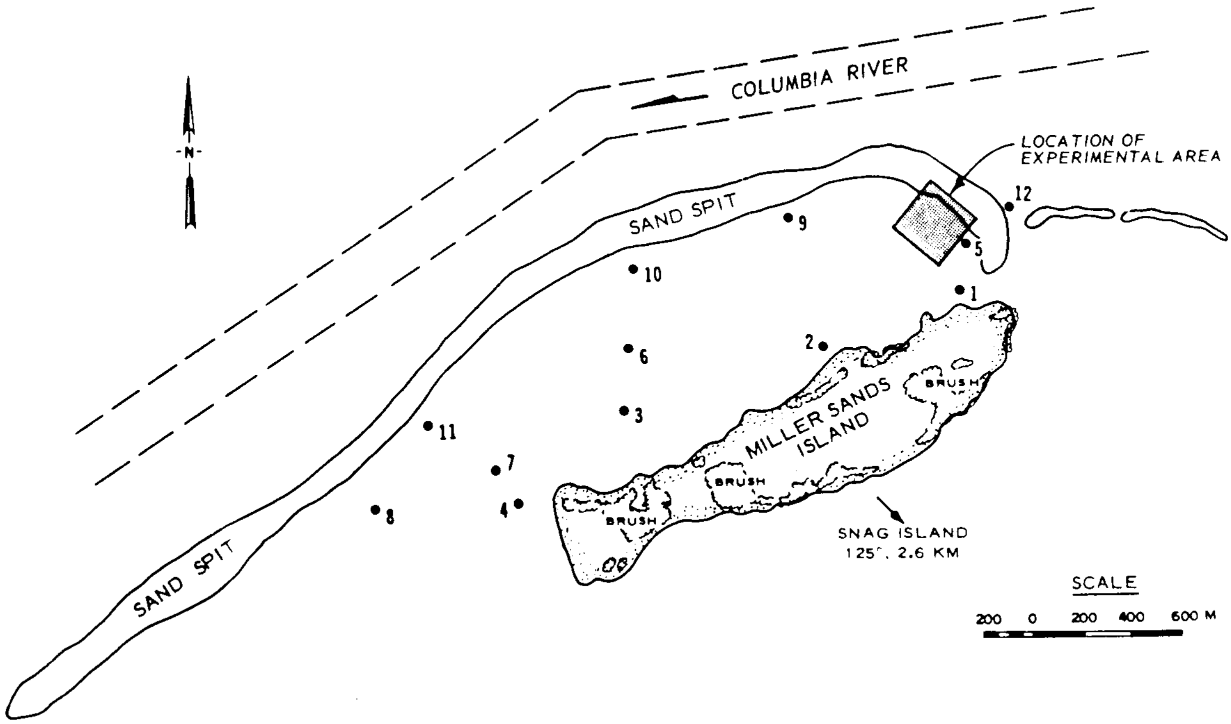

Figure 5. Field Location and Placement of Macrobenthos, Nekton and Water Quality Stations Within the Cove at the Miller Sands Habitat and Marsh Development Site.

30. Stations were marked by bouys or fence posts to aid in relocating sites throughout the study period. Contour elevations and station locations were verified by the Portland District, Corps of Engineers.

31. Throughout the post-operations study (July 1976-July 1977) the Pacific Northwest was experiencing a 100 year record draught. Due to this situation extreme low-flow conditions prevailed at Miller Sands making it necessary to adjust certain sampling schedules. These adjustments are shown in Table B1.

Sampling Program

32. Zooplankton populations were sampled with a 12.7 cm (5 in.) diameter Clark Bumpus sampler with a number 6 (0.24 mm) net and a digital recording flow meter. Five minute horizontal surface tows were made at four locations during each of the nine baseline surveys. Tows were made during daylight hours at mean and high tides in March, May, July and August 1975. Samples were taken only at high tide thereafter because shallow water in the cove prevented proper gear function. Tows were made between stations 5 and 6 and between stations 10 and 11 in the cove; the other two sites were located outside the cove at stations 12 and Snag Island. Samples were preserved in 10 percent buffered formalin solution and returned to the laboratory for identification and enumeration.

33. Samples were treated with a vital stain (Rose Bengal) and allowed to set for at least 24 hours. After an initial examination, samples containing large numbers of organisms or detritus were subsampled with a four-chambered plankton splitter. Organisms from at least two chambers were counted and a comparison was made to assure uniformity between splits. Excess liquid was removed from samples by filtering through a No. 20 screen, remaining material was placed in culture dishes for examination.

34. Zooplankton were identified to genus (Pennak 1953, Ward and Whipple 1959) and counted with the use of a sterozoom dissecting microscope. Developmental stages of the order copepoda were grouped and recorded as copepodites. Rotifiers, present during all sampling periods,

were not included due to the loss of these small organisms through the .24 mm sampling net. Two genera, Brachionus sp. and Asplancha sp. of this class were common.

35. The volume of water strained, during each 5 minute tow was determined from the area at the mouth of the sampler, number of revolutions registered by the flow meter and a clibration factor for the meter. All organisms in a sample or subsample were counted and the number per cubic metre (N/m^3) calculated.

36. Water quality parameters were monitored at all stations during the nine surveys of the Baseline Inventory (Table B1). These samples were collected at mid-depth during daylight hours (0700-1900).

37. Water depth was determined with a Ross Sportsman sounder or a lead line. Temperature, conductivity, and salinity were measured with a Beckman Model RS5-3 salinometer. *In-situ* turbidities were measured by the nephelemetric method and recorded in Formazin Turbidity Units (FTU). An H.F. Instrument Model DRT100 meter was used during the first three surveys; thereafter, a flow-through Hach "Surface Scatter" Turbidimeter was used. A Leeds and Northrup Model 7404 meter was used to record pH. The modified Winkler System (EPA 1974) was used for on-site calibration of a USI (Model 57) dissolved oxygen meter which in turn was used for *in-situ* measurements.

38. Water samples used for the determination of dissolved nitrogen saturations were collected in BOC bottles, chilled and returned to the Prescott Facility for analysis with a Van Slyke Blood Gas Apparatus (Van Slyke-Neil 1924).

39. Two additional water quality parameters were monitored during the Post-operation Phase of the Miller Sands study. Total Alkalinity was determined by the indicator method as described in Standard Methods (EPA 1974). Ammonia (NH_3N/l) concentrations were monitored with an Orion Model 407 specific ion meter and ammonia electrode Model 95-10.

40. Methods of collection and analysis remained consistent during all fifteen surveys. With the exception of dissolved nitrogen, water quality parameters were monitored and analyzed on site. Table B2 lists the parameter, standard units and symbols used in reporting water quality at Miller Sands.

41. During the six post operational surveys at Miller Sands samples were to be collected four times at thirteen stations. Each station was to be monitored on flood and ebb tides, between 0700-1900 (day) and at night between 1900 and 0700 hours. After the first two surveys (July and September 1976) it was determined, this schedule could not be adhered to because of time constraints and bathmetric limitations within the cove resulting from the prevailing low-flow conditions in the river.

42. After a review of available data it was decided that, due to the close proximity of stations and homogeneity of water quality at all stations in the cove, a reduction in number of stations would have the least affect on final information. Thus, nine stations were established two (C and E) associated with the experimental marsh area, and five (2,3,6,10,11) in the cove. Station 1 located in the channel betwe'n the island and sandspit provided a reference to inflowing water while Station 12 provided a reference with ambient river conditions (Figure B4). Water

sampling was synoptic with nekton collection period.

43. A beach seine was fished at five sampling sites during each of the baseline surveys. Sites 2 and 3 on the main island and 10 and 11 on the sandspit were within the cove (Figure B5). Station 12 was located on the channel side of the island to provide a reference to the fish present in the area and also timing of anodromous fish migrations. The beach seine was constructed of 12.7mm stretched mesh, nylon web and measured 76.2m long by 3.7m deep. Sampling procedure was to anchor the bunt end of the net on the beach then pay the net over the bow of a 5m outboard-powered boat while backing away from the beach at a 45-60 degree angle. When fully extended the net would be returned to the beach in a 135-120 degree sweep. Area sampled was approximately 0.9 hectares depending on current, tides and bottom configuration. Captured fish were eased to one end of the seine, transferred to tubs, identified, counted by species and returned to the river. A subsample of 10 fish per species were measured (fork length in mm) and weighed (gm). A scale sample was removed for aging.

44. During the post-operational phase of the study a destructive and non-destructive sampling procedure was employed to determine the species, numbers, length, weight, age of dominant species, and food habits of nekton present in the Miller Sands cove. Fyke (hoop nets with wings) nets and the previously described beach seine were used to collect nekton at 12 sampling sites throughout the cove.

45. Fyke nets used were winged D-shaped hoop nets with 12.7mm stretch mesh to the first fyke, remainder of the net was constructed of

.64mm stretch mesh. Wings, on both sides, were 3m long by .9m deep and and were 12.7mm stretch mesh. Five fyke net stations (A,B,C,D,E) were located on the .3 metre contour elevation at the five transects established in or near the experimental intertidal marsh habitat site. A fyke net was also fished at Station 6 near the center of the cove. Nets were fished twice (day and night) during each survey. Fyke nets were set at low water with the axis parallel to the high-low elevation gradient and the hoop opening directed toward the upper elevation. Wings were set to direct fish into the trap during the receding tide. Traps were harvested and reset at the next low water.

46. Six beach seine stations were located within the cove; stations 2,3,10, and 11 were fished during the baseline inventory. Two additional stations were added near the marsh experimental area. Station 5 was located at the head end of the cove between transect A and B while Station 9 was located on the sandspit downstream from the marsh area. Station 12 the river reference site was discontinued. Beach seine stations were sampled during two time period 0700-1900 hours and 1900-0700 hours between mid-flood and mid-ebb tides.

47. All organisms captured were identified to species, counted, and rough sorted into the following length categories. Fish whose total length was between 0-100mm were separated into 25mm groups; those between 101-300mm in 50mm groups; all fish over 300mm were placed into 100mm groups. Ten fish of each species and size group were sacrificed at each station during all surveys. Speciments were preserved in 10 percent buffered formalin and returned to the National Marine Fisheries Service, Hammond

Facility, where they were measured (total length in mm) and weighed (gms). Scale samples were taken for age determination and stomachs removed for a food utilization study.

48. Seven benthos stations were sampled (Table B1) during the nine baseline surveys (March 1975-May 1976). A $0.1m^2$ sample was collected by combining two grabs from a $0.05m^2$ Eckman dredge. Six paired replicate samples were collected at each station during each of the nine surveys. Paired samples were washed through a number 30 seive (.586mm) which is recommended by Schlieper (1972) for sampling macrobenthic organisms. Material retained on the screen was preserved in 10 percent buffered formalin containing Rose Bengal, a vital stain. Samples were returned to the laboratory for identification, enumeration, and weighing of the dominant organisms.

49. After an evaluation of benthic data collected during the baseline inventory it was decided that a reduction in sample quantity, (from $0.1m^2$ to $0.05m^2$) and in number of replicates (from six to three), would not statistically reduce the quality of the data. Sampling stations at Snag Island and at river Station 12 were discontinued prior to the post-operational phase of the study.

50. Twenty-six benthos stations were sampled during the post-operational phase (July 1976-July 1977) at Miller Sands. The eleven stations located within the cove were established on a grid pattern which provided complete coverage of the cove's substrate. Five of these stations (2, 3, 6, 10 and 11) were established during the baseline inventory. Fifteen additional stations were located along the five transects established

in or near the marsh experimental site. The three sites on each transect correspond to the .3, 1.2 and 1.8 metre contour elevations.

51. Samples within the cove were collected with the $0.05m^2$ Eckman dredge during high water. Samples from the fifteen sites located in the intertidal marsh development area were collected by hand during low ebb tide. Hand dug samples were taken from an area defined by a $0.05m^2$ frame to a depth of 10cm. Replicate (three) samples were placed in individual containers and transported to the boat for washing.

52. Samples were preserved and returned to the laboratory where all organisms were removed from the debris, identified, counted, and weighed. Mollusks were weighed separately and estimates of total biomass per sample follow procedures as described by Weber (1973).

53. Sediment samples were collected synoptically with benthos sampling. A coring device which measured 3.8cm inside diameter was used to collect sediment samples to a depth equaling the penetration of the benthic sampling device. Sediment samples taken from the Eckman dredge were measured for depth thus providing a gauge on which to establish uniform penetration of the dredge into the substrate during each replicate grab.

54. Samples from the intertidal marsh area were taken from the sampling frame prior to removal of the benthic samples. Each sediment sample was placed in a plastic sack, marked by station and grab (replicate) number and sent to a testing laboratory for analysis. Particle size was determined by standard seive and pipette procedures. The course fraction >.063 (silt and clay) was broken down only if that fraction was

20 percent or more of the total sample (if less, then only total percent fines is reported).

55. The organic content (volatile solids) found in a sediment sample was determined by standard procedures as outlined by Standard Methods (EPA 1974), and reported as percent volatile solids.

56. After each survey was completed, preserved nekton samples were brought to the NMFS Hammond Facility where they were measured (total length in mm) and weighed (total weight in gm). A subsample from each species at each station was designated for stomach analysis. The guts were cut at the throat and junction of the pyloric caecae (if present), removed, and placed in the appropriate vial according to the following length categories:

0 - 25mm	151 - 200mm	501 - 600mm
26 - 50mm	201 - 250mm	
51 - 75mm	251 - 300mm	
76 - 100mm	301 - 400mm	
101 - 150mm	401 - 500mm	

57. The vials were labelled, filled with 5 percent buffered formalin solution, and stored until analysis. The study design specified examining 10 stomachs containing food for each length category of each species at each station. This, of course, was not possible; however, all stomachs containing food (up to 10) were saved and the numbers of empty stomachs were recorded.

58. Stomach analysis followed Borgeson's technique (Borgeson, 1966). Each month vials were labelled for each station according to total length into which each fish species was grouped. Stomachs thought to contain food were put into each vial and covered with 10 percent formalin. Known empty stomachs were recorded. Later analysis showed some of the guts in

the vials to be empty and data were adjusted accordingly. One disadvantage to Borgeson's technique is that it does not allow computation of frequency of occurrance.

59. Each vial was later emptied into a watch glass and organisms were identified to the lowest feasible taxonomic category and enumerated. The volume of each category was determined by water displacement. For some of the small items, such as cladocerans and copepods, it was necessary to group specimens from several stations to have enough mass to record a volume. Accuracy of laboratory equipment had a lower limit of 0.05ml. Volumes less than this were recorded as trace.

60. Identifications of organisms were based upon the following sources: Banner (1948), Bradley (1908), Brodskii (1950), Chu (1949), Jaques (1947), Mizuno (1975), Needham and Needham (1962), Pennak (1953), Smith and Carlton (1975), Smirnov (1971), Usinger (1956), and Ward and Whipple (1918).

PART 3: RESULTS AND DISCUSSION

Zooplankton

61. A list of zooplankton taxa, and genera of other aquatic organisms found in plankton nets during surveys at Miller Sands, 1975 - 1976 is shown (Table B4). Taxonomic categories identified included 12 genera of Cladocera, 4 Copepods (and the juvenile form Copepodites), 4 taxa representing insects and larval fish forms. Ostrocoda, Anostraca, and Amphipoda were also represented. Although not included in the zooplankton list, two genera of the class Rotifera, *Brachionus* sp. and *Asplancha* sp. were common.

62. Results of zooplankton sampling during the nine baseline surveys are presented in Appendix Table B1, and are summarized in Table B4. Total population densities were numerically larger at cove stations (5 and 11) than at the river (12) or Snag Island reference stations. Total densities at stations 5, 11, 12 and Snag Island were 2466/m^3, 3208/m^3, 1975/m^3 and 1623/m^3, respectively. Zooplankton densities were low (21.5/m^3) in March 1975; they increased with increasing water temperature reaching a peak of 5,984/m^3 in September 1975. By November, the number of zooplankton per cubic metre had sharply declined (66/m^3); thereafter declining through March 1976.

63. Three taxa dominated the zooplankton community at Miller Sands. The two cladocerans *Daphnia* and *Bosmina* and the copepod *Cyclops*. These three organisms represent 96% of the total zooplankton collected and were present at all sampling sites during the entire survey.

64. *Daphnia* the overall most dominant taxa increased to peak abundance in September ($5,164/M^3$), then declined sharpley (see Table B5). *Daphnia* was dominant during August and September.

65. The population densities of the copepod *Cyclops* follow a normal curve, increasing gradually from March 1975 to September, then declining to a low in March 1976. *Cyclops* was dominant during the January survey, 1976.

66. *Bosmina* increased in abundance during May and reached a peak in July, decreasing during August and September, the period of highest water temperatures, increasing again in November as temperatures declined. *Bosmina* was the dominant zooplankton in May, July, and November, 1975, and again in May 1976.

67. Seasonally abundant taxa included *Eurytemora* sp (August to September) and *Alona* sp in May. *Alona* were present in small numbers throughout the year.

68. The population density of zooplankton at Miller Sands was lower in March and May 1976 than during the same period in 1975. This reduction in zooplankton was also reported by (Beak, 1977) at Columbia River kilometre 116.7.

69. Zooplankton were excluded from post-operational surveys because it was felt a qualitative analysis, based on bimonthly sampling, was not feasible.

Water Quality

70. Water flow conditions in the Columbia River were high in 1975, average in 1976, and were exceedingly low during the winter of 1976 and the spring-summer of 1977. Water quality parameters that were manifested as a result of these changes in flow probably overpowered subtile changes that could have developed as a result of the habitat improvement project at Miller Sands. However, all water quality parameters were analyzed in relation to differences between stations, between years, between ebb and flood tides, and between day and night. In addition, an analysis was made of all parameters during 1976-1977 comparing the cove stations, the habitat improvement area and the river site.

71. Water temperatures reached a maximum of 21°C earlier (July) in 1976 than in 1975; temperatures peaked at 20°C during August of 1975. Generally, there was less than 2°C difference between stations, and usually less than 1°C between tides, and between day and night. Mean temperature and ranges of all samples taken during the study are shown in Figures B6 and B7. Minimum water temperatures normally occur in the Columbia River during January/February; they were measured January of 1976.

72. The pH ranged from a low of 6.6 to a high of 9.0 during the study. The low occurred at Station 12 during the fall (September) of 1975. The high occurred at Station 11 during July 1976. Normally, high alkaline waters originate east of the Cascade Mountains and increase the pH of the waters of the Columbia River during spring run-off which peaks in June at Bonneville Dam (CRK 224, RM 140). The rain west of the Cascades normally causes high water in the tributaries during the winter and this

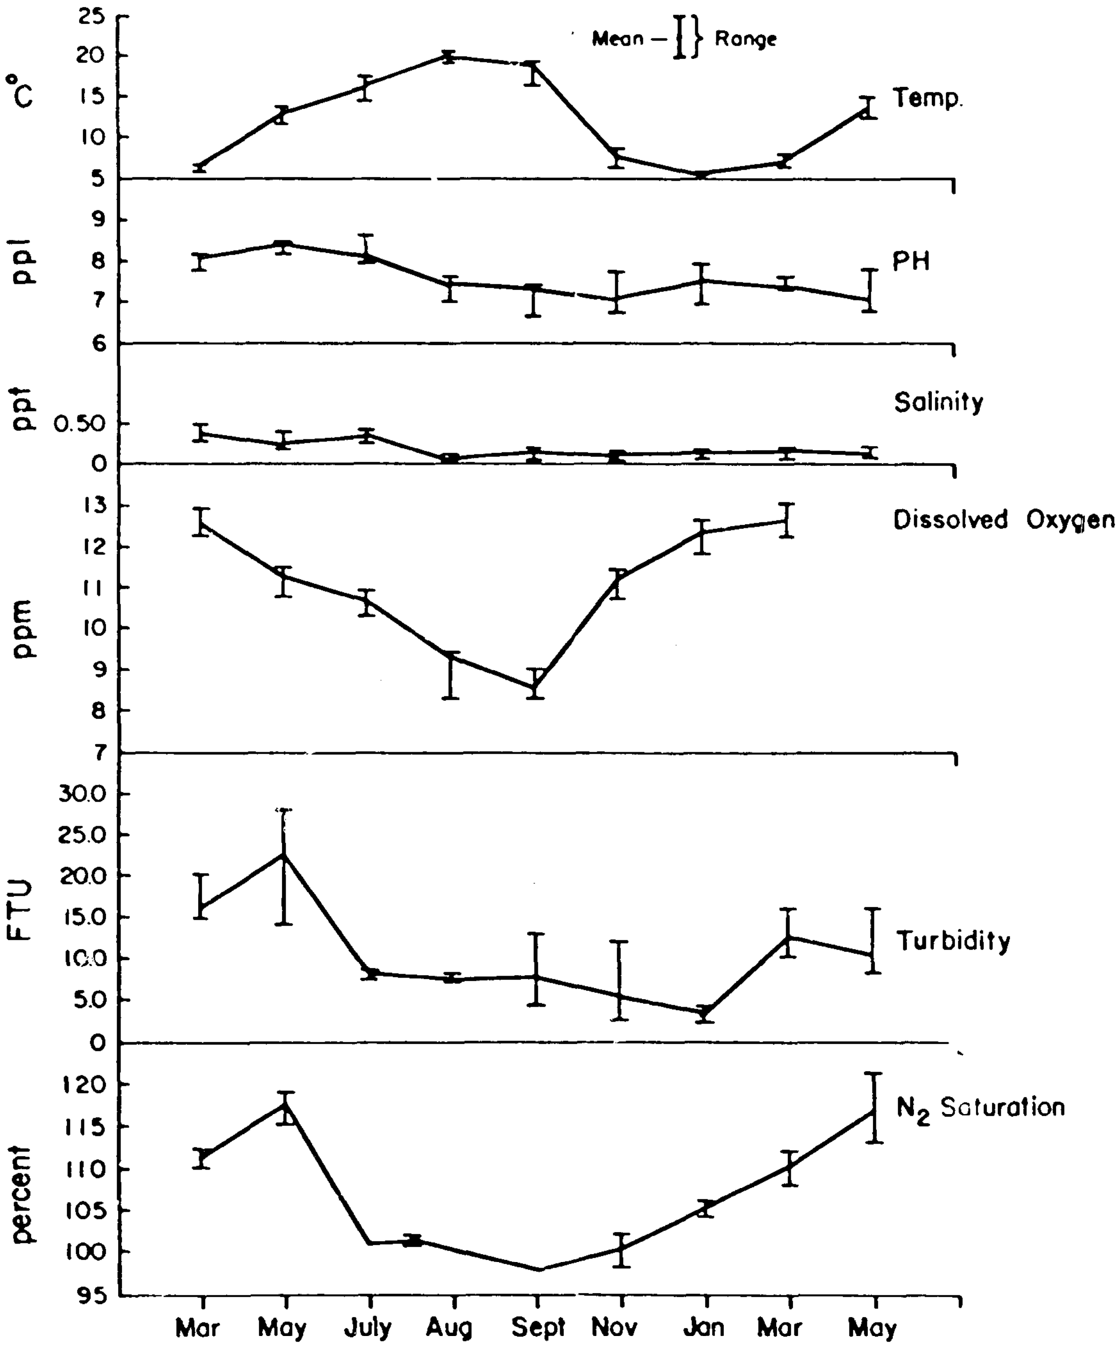

Figure B6. Mean and Range of Water Quality Parameters Taken at High Tide at all Stations, Miller Sands, 1975 - 1976

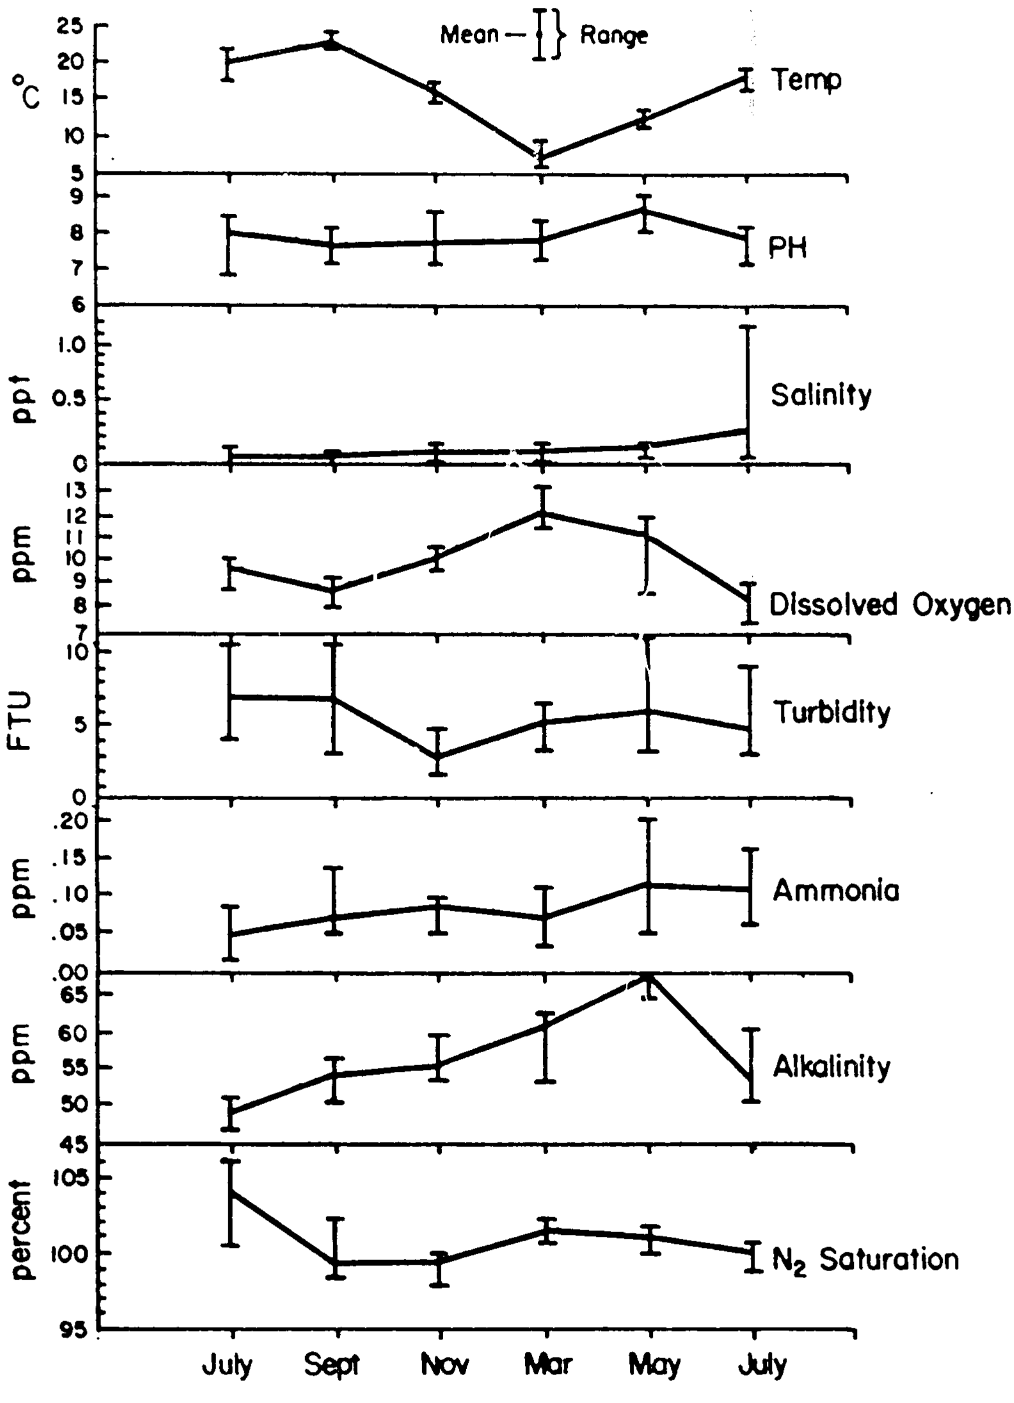

Figure B7. Changes in Water Quality Parameters, 1976 - 1977, at Miller Sands run-off tends to lower pH in the Columbia River. Range of pH seldom varied 1.0 unit between stations, between high and low tides, and between day and night.

73. Salinity measured at the Miller Sands water quality stations did not exceed 0.5 0/00 except during July (Station 12) of 1977 where it reached 1.22 0/00 on a day/ebb tide. The increase in salinity could have been the result of the removal of 9 million cubic yards of material from the Columbia River Bar during the spring and summer of 1977. The remc··al of this material lowered the channel depth from 48 feet to 53 feet, with the exception of the one measurement above 1.0 0/00, rarely did salinity exceed 0.5 0/00 which normally would be conceded to fall within the accuracy of conventional measurement instrumentation.

74. Dissolved oxygen levels were compared throughout the study at stations 2, 3, 10, 11 and 12. High (13.0 ppm) levels occurred during March of 1975, 1976, and 1977. Low values occurred during July, August and September but rarely dropped below 8.0 ppm. There were no significant differences found in dissolved oxygen levels (at stations 2, 3, 10, 11 and 12) between stations, between high and low tide, or between day and night. The highest range of O_2 values occurred during May 1977 at Station E, where the difference between the night ebb (8.7 ppm) and the day ebb (11.6 ppm) was 2.9 ppm. The ranges between stations, tides and day/night rarely exceeded 1.5 ppm and were always at acceptable ranges for aquatic organisms.

75. Water turbidity reached a maximum of 28 FTU's at Station 12 during May 1975. In general turbidity was higher at comparable stations

(2, 3, 10, 11, 12) in 1975 decreased from 1975 levels during 1976, and were at all time lows in 1977. Turbidity at stations 2, 3, 10, 11 and 12 rarely exceeded 10 FTU's during the 1977 sampling periods. However, 1977 was a record low flow year and turbidity in the lower Columbia River in general was exceedingly low. There was no significant difference between stations, tides, or day/night relationships.

76. Dissolved nitrogen gas (N_2) saturation reached a high 121.0 percent at Station 12 during May of 1976. Station 12 was the outside (river side) station and usually was higher than the cove stations (2, 3, 10, 11) and the intertidal stations (A through E) where the marsh habitat experiment was in progress. In general N_2 saturation that exceeds 115 percent for extended periods could result in aquatic organism fatalities in the shallow cove areas of Miller Sands. High saturation values can be directly correlated with peak run-off from east of the Cascades, and the spilling of large quantities of water through the numerous hydroelectric dams on the main stem Columbia and Snake Rivers, (the Snake River run-off peaks in May, the Columbia River peaks in June).

77. Ammonia was added to the water quality parameters in July of 1976. In general the range did not exceed .15 ppm and then only at three stations; i.e., Stations C, D, and 1. Maximum levels occurred at station 1, during September 1976 during a day/flood. Maximum levels occurred at Stations C and E during May 1977 at all tidal cycles, day and night. The highest level (0.20) occurred on the night ebb at Station E. In general higher levels occurred at the cove stations, 10 and 11, during the night than during the day during May 1977, but these differences overall were not statistically significant.

78. Total alkalinity was the second added parameter in July of 1976. Highest values occurred during May at the cove stations, and at the marsh habitat sites that were sampled during May 1977; i.e., Stations C and E. The range of alkalinity generally increased with time from July 1976 to July 1977 (see Figure B7). No visible trends were apparent in the station comparisons, nor with tidal cycle or day night comparisons.

79. The intertidal or marsh habitat sites were compared to the cove sites 2, 3, 10 and 11, and to the outside river site (Station 12) for the period July 1976 through July 1977. In general, the river was cooler than the cove, temperatures varied several °C, indicating a general warming of the cove and marsh habitat area. However, the warming of the cove had little effect on DO levels.

80. N_2 saturation levels were slightly and consistently higher at the river stations except when river water entered the cove through the cove channel during high river run-off. Turbidities remained fairly constant and at a low level throughout the study inside and outside the cove.

81. The 1976-1977 levels of turbidity rarely exceeded 10 FTO's, which by any standards is exceedingly clear water. More definitive work needs to be conducted on ammonia levels because during May 1977 there appeared to be differences between day and night levels at stations 2, 6, 10, 11, C and D, but these differences did not manifest themselves in the July 1977 sampling period nor at any time prior to the May sampling period. Data for water quality parameters can be found in Appendix Tables B2 and B3.

Nekton

82. A total of 13,755 fish representing twenty species were captured during the fifteen bimonthly surveys at Miller Sands (March 1975-July 1977). A list of these fish in descending order of abundance is presented in Table B6. Four species accounted for 93% of the total catch: juvenile chinook salmon, *Oncorhynchus tshawytscha*; peamouth, *Mylocheilus caurinus*; starry flounder juveniles, *Platichthy stellatus*; and threespine stickleback, *Gasterosteus aculeatus*.

83. Total catch data by station and survey are presented in Appendix Table B4 and Appendix Table B5. Juvenile chinook salmon, threespine stickleback and juvenile starry flounder were captured at all beach seine stations and were present during each survey. Peamouth chub occurred at all stations but were not captured during the March 1975 or January 1976 surveys (Figure B8).

84. Monthly catches of the four dominant species at beach seine sites during the baseline inventory (March 1975-May 1976) are presented in Figure B8. Figure B9 is the monthly catches of these species during the post-operational phase (July 1976-July 1977). The square root transformation of the total monthly catch data is used.

85. Monthly catch and catch per unit of effort for the period March 1975 to May 1976 is presented in Table B7, and represents catch by beach seine, during daylight hours only. In July 1976 the fishing effort was expanded to include fishing with fyke nets and at night. Thus, Tables B8 through B11 are summaries of the monthly catch of the dominant species at all stations, with beach seines at night (Table B8), daytime (Table B9)

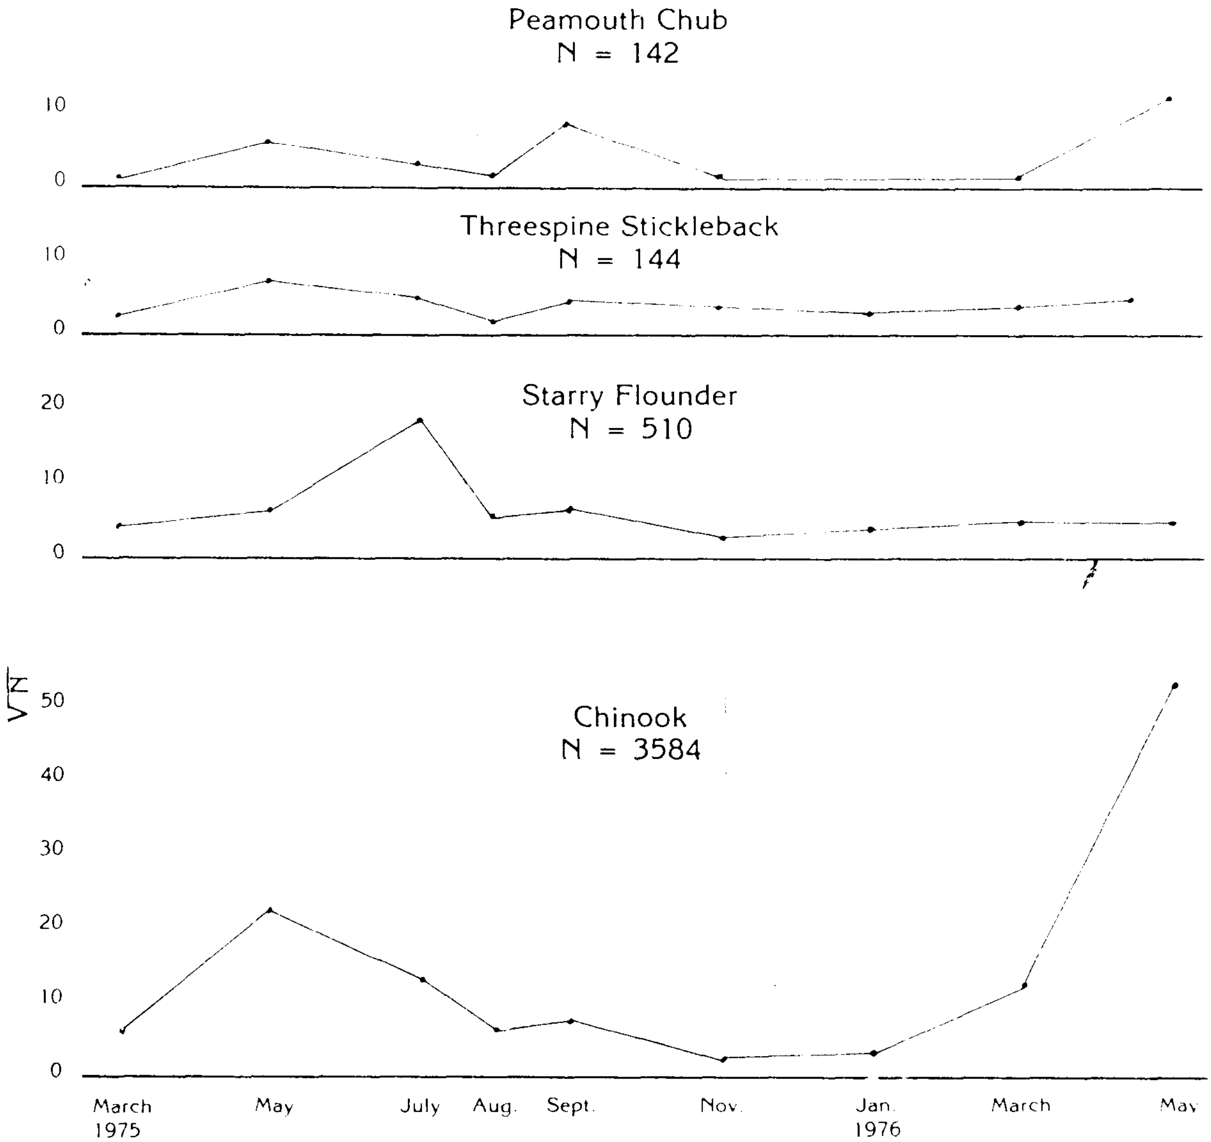

Figure B8. Monthly Catches of Nekton (expressed as $\sqrt{N}$) of Important Species Captured by Beach Seine at Miller Sands, March 1975 - May 1976

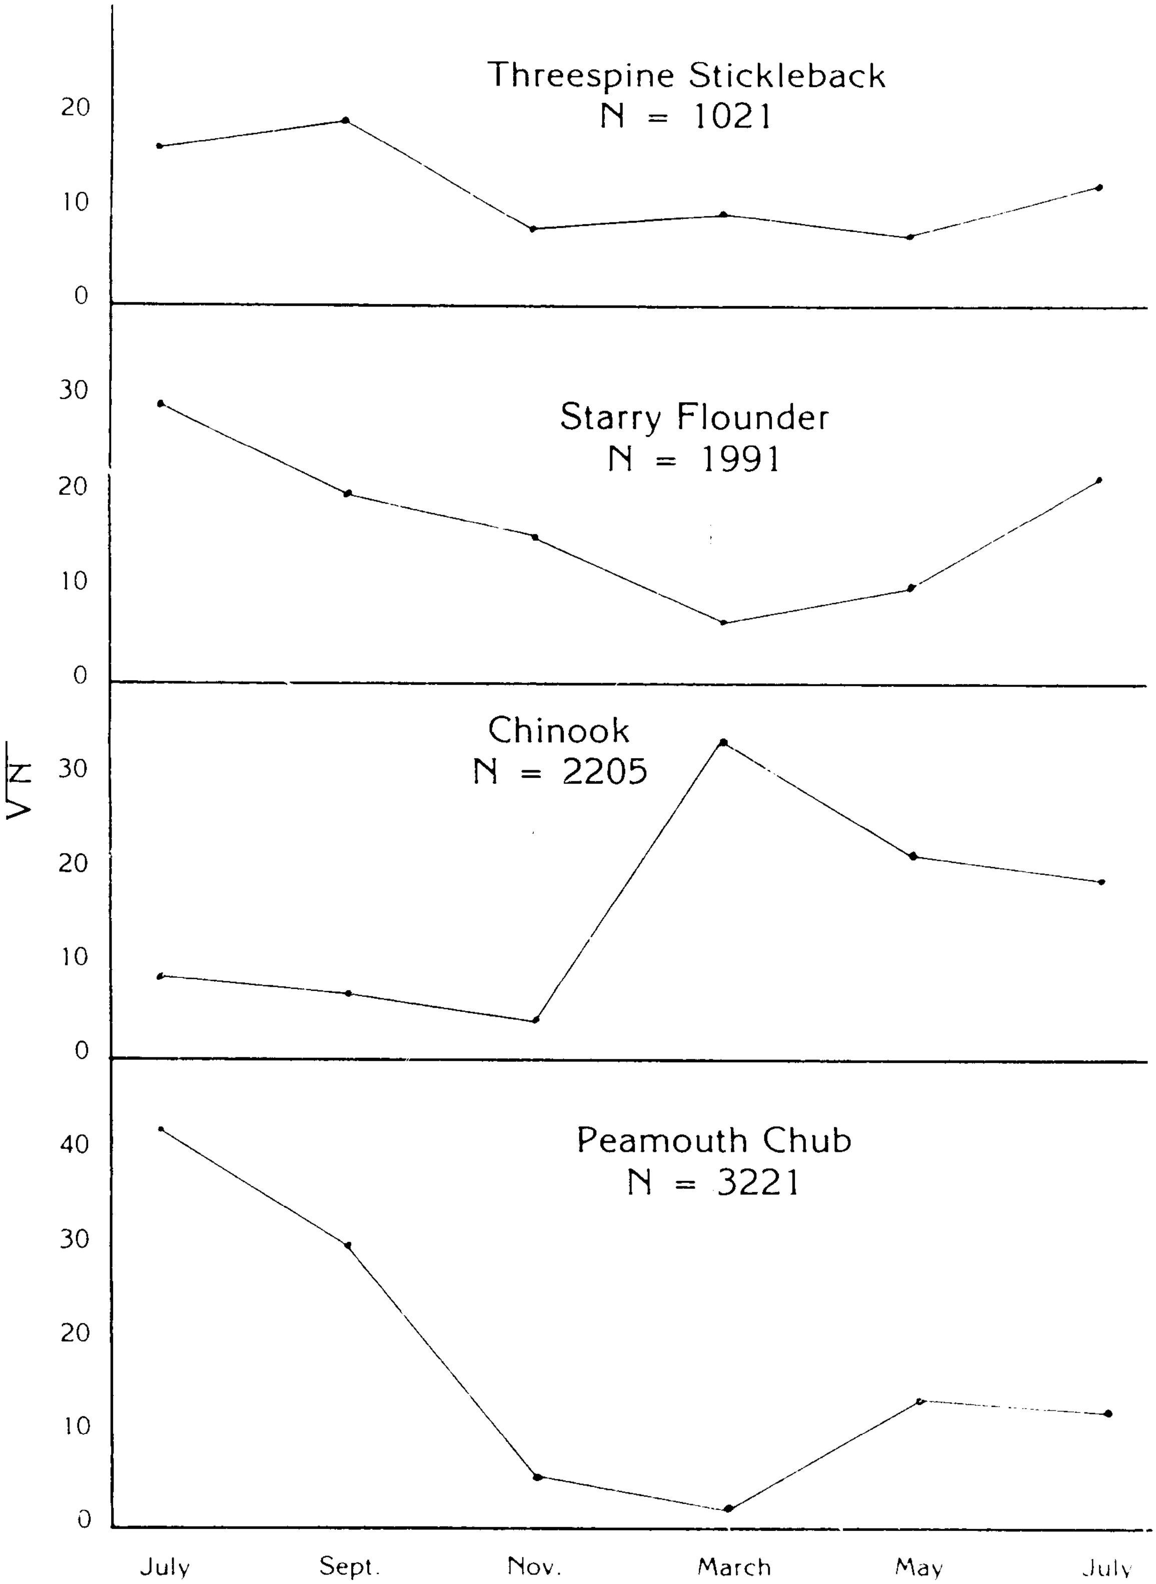

Figure B9. Monthly Catch of Important Species of Nekton (expressed as $\sqrt{N}$) Captured with a Beach Seine and Fyke Nets at all Stations, July 1976 - July 1977 and for fyke nets at night (Table B10) and during the day (Table B11). The tables include total fish captured and catch per unit of effort. A summary of CPUE findings for the entire study period is given in Table B12.

86. Juvenile chinook salmon were the most important economic species and represent 42 percent of the total catch. Chinook juveniles were the numerically dominant species captured at Miller Sands in March and May 1975, 1976 and 1977, also during August, September (1975) and in July 1977 (Figures B8 and B9).

87. During the baseline inventory 2446 juvenile chinook were taken at Station 12, the river index site (See Table B7). This accounts for 68% of all chinook captured during the baseline study.

88. The peak catch of juvenile chinook occurred in May 1976. The respective catch per unit effort (CPUE) 536.4 (Table B12). The early peak during March 1977 may be associated with the low flow conditions which prevailed in the Columbia River during 1976-1977.

89. Peamouth, *Mylocheilus caurinus*, was the dominant species July and September 1976 at Miller Sands during the post-operational phase. This increase was mainly due to the initiation of night fishing during this study period. The night catch of peamoush was 2126 (Table B8) as compared to 664 fish taken during the day (Table B9). The overall peak catch of peamouth occurred in July 1976 when 1442 individuals were captured at Station 5 during the night survey (Table B8).

90. Peamouth were also the most common fish captured by fyke nets at the march development site; of 702 fish captured 434 were peamouth; 121 during the night (Table B10), and 310 during the day (Table B11).

91. Juvenile starry flounder were captured during each survey and are the third most common species present at Miller Sands. Peak occurrence during the three years was during July 1976 and the peak CPUE (71 fish) occurred the same month.

92. Threespine stickleback were also present at Miller Sands during all surveys and were captured at all sites. This species ranged from a low CPUE of 0.4 in August 1975 to a peak of 34 fish in September 1976 (Table B12).

93. Although these four species represent 93% of the total catch at Miller Sands, additional economically important sport or commercial species were captured. These were coho, chum, and sockeye salmon, *Oncorhynchus spp*; steelhead and cutthroat trout, *Salmo spp*; longfin smelt, *Spirinchus sp*; the eulachon, *Thaleichthys pacificus*; and the American shad, *Alosa sapidissima*.

94. During the baseline inventory scale samples were collected for age determination of the important species. Ten fish of each major species were weighed, measured and age determined. During the post-operational phase this effort was expanded in conjunction with the food utilization study. Ten fish from each of the following length categories were sampled at each site during each survey.

0 - 25mm	151 - 200mm
26 - 50mm	201 - 250mm
51 - 75mm	251 - 300mm
76 - 100mm	301 - 400mm
101 - 150mm	401 - 500mm

95. The age, number, mean weight and length of the five dominant species taken during the post-operational surveys is presented in Appendix Table B7.

96. Age for juvenile chinook, peamouth and largescale sucker was determined from scale annuli. The age of threespin stickleback and starry flounder was determined by the length frequency method. (Jones and Hynes, 1950; Haertel and Osterberg, 1966; Scott and Crossman, 1975).

97. Fish in the first year (0-1 year old) were called age class 1. Fish older than age class 4 (3-4 years old) were combined under the heading age class 4.

98. During the baseline studies the age class, mean weight and length was determined for three species; chinook, starry flounder and peamouth chub. Age determination was made for the above dominant species and also for threespine stickleback and largescale sucker during the post-operational phase. The age class by month for the three dominant nekton species captured at Miller Sands during all surveys is shown in Table B13.

99. Juvenile fall chinook age class 1 dominate the chinook catch in March, May, and July during all three years. Spring chinook, which migrate during their second year, were captured during late summer and fall and may remain in the estuary until the following spring. This is indicated by the 22 age class 2, and the nine age class 3 fish captured in March 1977. The larger percentage of these older chinook captured during the spring of 1977 is probably due to the low flow conditions. Alabaster (1978) states that significant numbers of chinook held over throughout the Columbia River in 1977. Mean weight and length by age class for these dominant species is presented in Appendix Table B6 and Appendix Table B7.

100. The mean weight and length for the 1175 juvenile chinook sampled during the Miller Sands surveys was 10.3 grams and 88.7 mm. Eighty-nine percent of juvenile chinook captured were age class 1, fall chinook.

101. Juvenile starry flounder (euryhaline species) is found throughout the lower Columbia River. Both age classes 1 and 2 were present during each survey. Older fish of this species are not usually taken in fresh water. The increase in those fish, age class 3, from July 1976 through July 1977 would indicate a change in conditions possibly due to low flow. Mean weight and length for the 1045 juvenile starry flounder was 10.5 grams and 76.4 mm. As with chinook age class 1, starry flounder age class 1 were the major class present at Miller Sands.

102. All five age categories of peamouth chub were present at the study area; 42 percent were age class 1; 32 percent age class 2; 37 percent age class 3 and 7 percent were age class 4, while 15 percent were older than age 4. Mean weight of the peamouth was 25.2 grams and mean length was 108.9 mm.

103. Nekton in order of mean annual abundance and average weight per individual for all species captured during the post-operational survey is shown in Appendix Table B8.

104. Student's t-tests were performed to determine if there was a difference between the night and day beach seine catches at Miller Sands during the post-operational surveys. At the 95 percent confidence interval there was no statistical reason to conclude the catches were different. The Wilcoxon-Mann-Whitney rank sum test was also performed with the same results.

105. Although statistically there appears to be no overall difference, there are monthly variations (Figure B10).

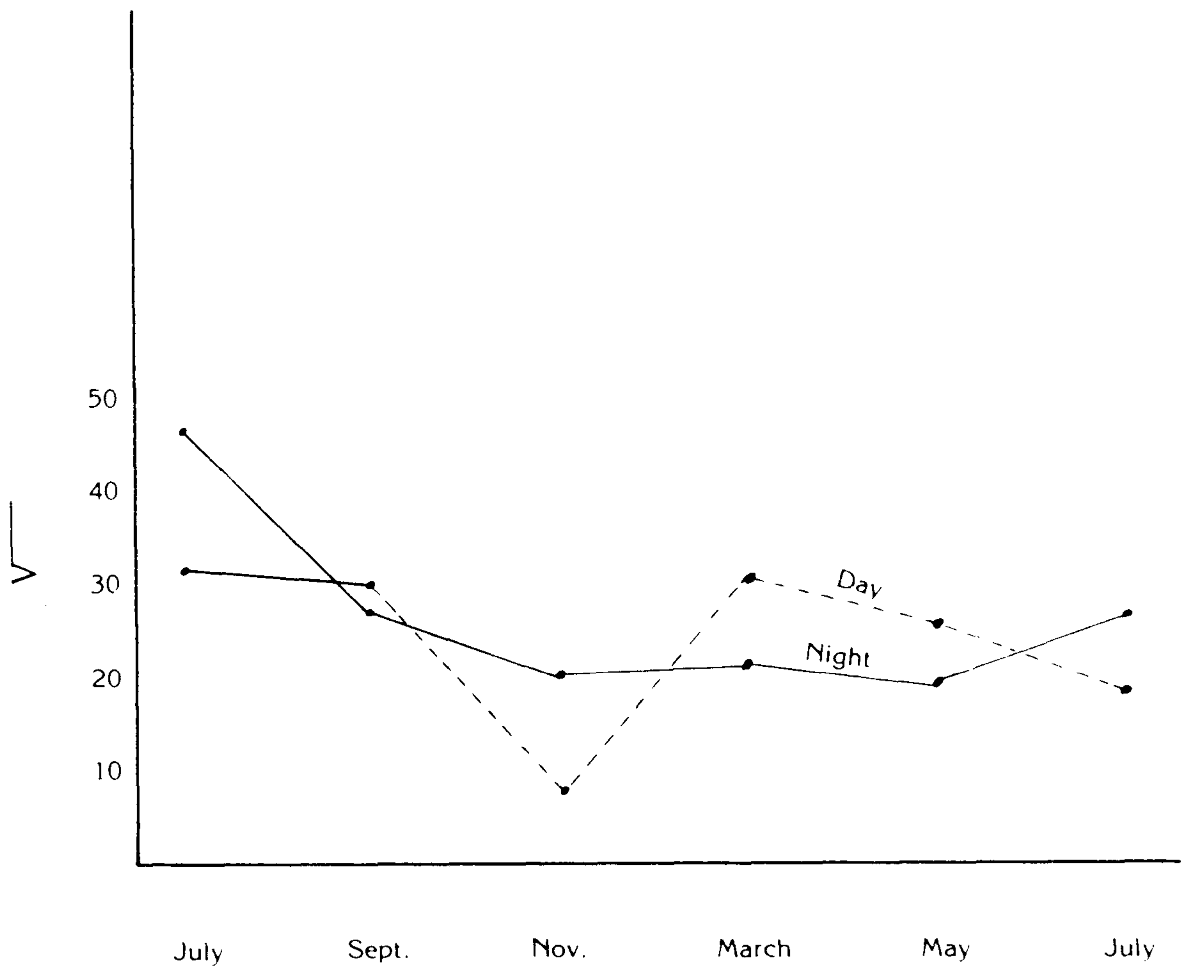

Figure B10. Variations Between Day and Night Beach Seine Catches at Miller Sands, July 1976 - July 1977 (Variations Expressed as the $\sqrt{N}$).

106. A comparison of the nekton captured by beach seine (during the day) at Stations 2, 3, 10 and 11 is shown in Table B14. These four stations were sampled during each of fifteen surveys, March 1975 to July 1977.

107. Total catch was highest during 1976, this reflects a catch of 388 chinook at Station 11 during May and also 368 starry flounder at Station 3 during July of this year. Both of these catches are above normal.

108. The number of fish captured during the three months of 1977 decreased from the highest level in March to the lowest value during any of the July surveys. The high catches at Station 2 and Station 3 during March 1977 reflect a larger than normal catch of juvenile chinook during this month.

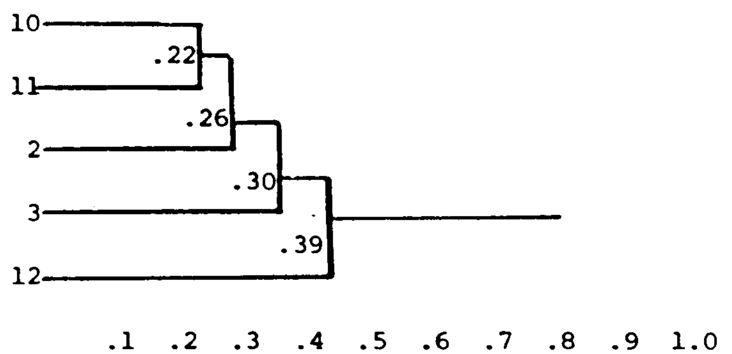
109. Changes between sites and stations during these three months generally reflect a higher than normal occurrence of a given species. An exception is the decreasing total catch in 1977 which again probably indicates changes due to the 100 year round drought during 1976 and 1977.

110. Beach seine sites during the baseline inventory and post-operational phase of the study are classified according to the number of nekton captured at each site. Fyke net sites in the intertidal area and at cove Station 6 are also classified from a data matrix from which a Bray-Curtis dissimilarity analysis was done (Clifford and Stephenson, 1976). A matrix was generated between all possible pairs of stations using the formula:

$$D_{jk} = \frac{\sum_i |x_{ij} - x_{ik}|}{\sum_i (x_{ij} + x_{ik})}$$

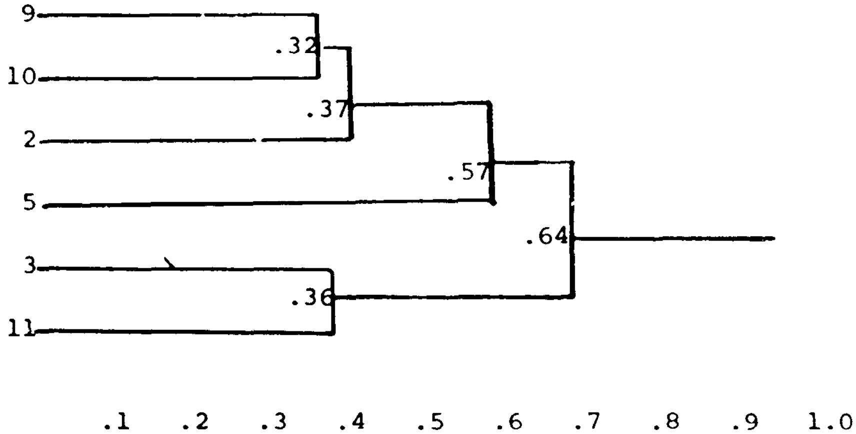
111. D is the measure of dissimilarity between stations j and k and x_{ij} is the square root transformed values of the ith species in the jth station. The value of dissimilarity is constrained between 0 and 1 where 0 represents complete similarity and 1 complete dissimilarity between stations. Stations were then clustered into similar groups using group-average sorting which joins the stations based on the smallest mean dissimilarity value between individual stations or groups of stations already joined.

112. Following are dendrograms of the Bray-Curtis treatment of combined data during the baseline inventory, post-operational cove stations and intertidal marsh habitat sites.



Baseline Inventory March 1975 - May 1976

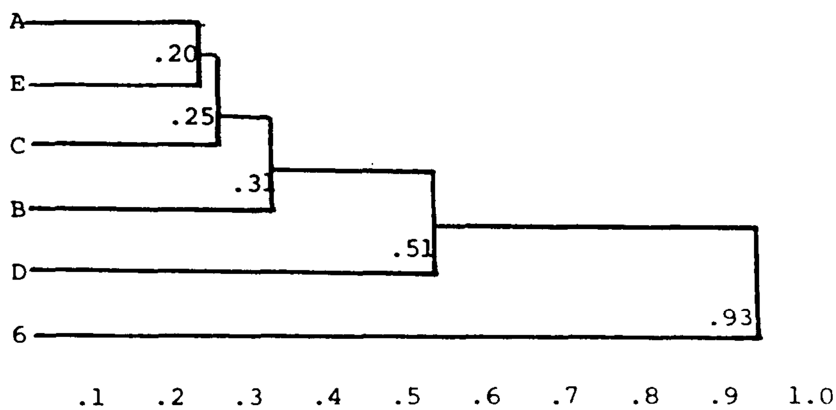
113. The dendrogram shows all stations joined at the .3 level are more similar than dissimilar. Station 12, the river index site, is the most dissimilar, while stations 10 and 11 are the most similar. Stations 10 and 11 are located on the Sand Spit.



Post-operational Cove Beach Seine Sites July 1976-July 1977

114. Stations 9 and 10 located on the sand spit are shown to be the most similar, Station 5 located on the sand spit at the upper end of the cove is most dissimilar. Stations 3 and 11 located at the downstream end of the cove are similar but dissimilar to those stations located upstream within the cove. This may be due to the low flood conditions during this period and the lower than normal water levels within the cove.

115. The following dendrogram is a comparison of the intertidal marsh habitat sites which were sampled by fyke nets. Also included is the cove fyke net station (5).



Intertidal Marsh Habitat Sites A Through D and Cove Fyke Net Site 6

116. The marsh reference sites A and E are most similar. Station D, the downstream intertidal site, is the most dissimilar of the marsh sites. This may be due to the large number of peamouth captured at this site during September 1976. Station 6, the cove fyke station, is the most dissimilar.

Benthos

117. A computer was used to examine some aspects of the 1975-1976 data. A dissimilarity matrix was generated between all possible pairs of stations using the Bray-Curtis Dissimilarity Index.

118. The value of dissimilarity is constrained between 0 and 1, where 0 represents no dissimilarity or complete similarity between the two stations. The stations were then clustered in similar groups using a group average sorting strategy. This strategy in which the stations are successively joined based on the smallest mean dissimilarity value between individual stations or groups of stations already joined.

119. The results of cluster analysis of the benthic data were compiled into a denogram (Figure B11). Species were grouped using similar techniques as the fish data except that species values were standardized using a square root transformation and by dividing each species value by the sum of the values for that species at all stations.

120. The biomass at each station was averaged throughout the year to show monthly and annual totals. All raw data can be found in Appendix Table B9.

121. All raw data was analyzed by computer to obtain the required tables and figures. The BraypCurtis dissimilarity analysis comparing stations, taxa, and time were not conducted as in the 1975-1976 study. The data were analyzed for monthly numerical abundance and comparisons made in abundance of taxa at subtidal and intertidal sites. All raw data has been compiled and can be found as a computer print-out in Appendix Table B10.

122. It was determined due to the relatively large sieve size some nematodes, although extremely numerous, were passing through the mesh and

quantification was not accurate. They were not enumerated as was done in 1975-1976. Insect families were combined into one heading -- insect larvae.

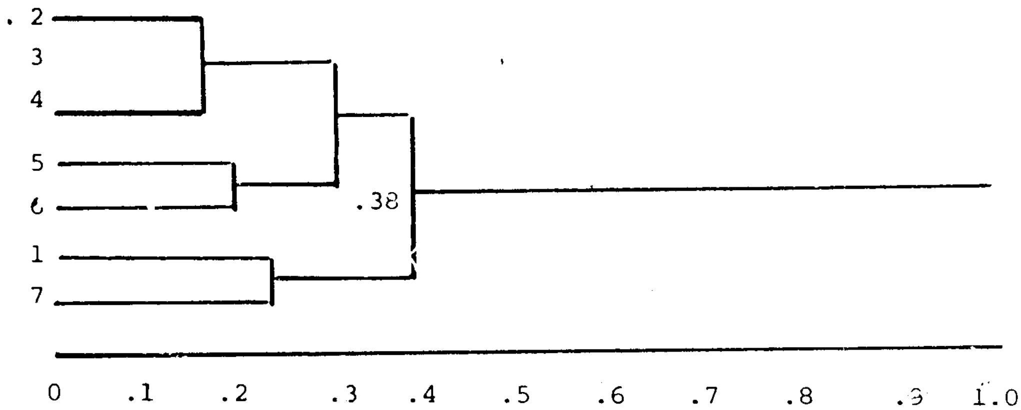
123. The sites fell into three similar groups. Stations 1 and 7 were similar in composition (Bray-Curtis value .23) stations 5 and 6 were similar in composition (.16). This grouping relationship is illustrated by the dendogram in Figure B11. Nematodes, *Neomysis*, Chironomidae and Oligochaete were most abundant at stations 2, 3 and 4 and least abundant at station 1 and 7. *Corophium*, *Corbicula*, Gastropods, Polychaetes and aquatic insects appeared to be equally abundant at all stations. *Anisogammarus*, Platyhelmenthes, *Adonata* were rare at all stations. Fish eggs were found only at station 7 in January and March 1975. These eggs were probably deposited by Eulachon, *Thaleichthys pacificus*, which is known to spawn during the winter in the mainstream of the Columbia River.

124. Stations were analyzed to determine seasonal trends in the benthic community. It was determined that the species composition and their number are relatively stable throughout the year. This is illustrated in Figure B11.

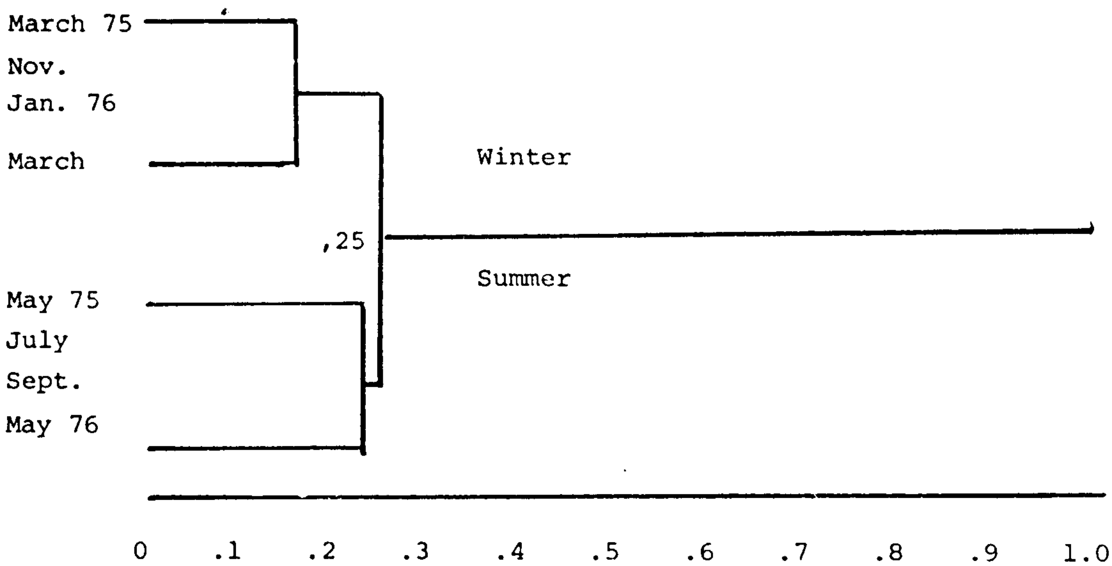
March, November, January exhibited similar species numbers (Bray-Curtis value .16) May, July, September, had a value of .23 and all stations were joined at .25. Analysis of species composition and seasonal trends demonstrated that there is more species variation between stations than there is from summer to winter. This analysis is important in demonstrating that each station has a characteristic community that

BENTHIC ORGANISMS - MILLER SANDS

March 1975 - May 1976



Site-Species



Time-Species

Figure B11. Dendogram's based on group-average sorting of Bray-Curtis dissimilarity values between all possible pairs of samples.

0 = Complete similarity 1.0 complete dissimilarity.

is somewhat stable throughout the year and differs from other areas in the river.

125. The wet weights of the six grabs at each station were averaged and converted to biomass in grams per square metre. This information shows monthly variations in biomass and is a means of determining the highest standing crop stations throughout the year. Station 3 clearly showed the greatest annual biomass of 371 grams (Table B15). Stations 2, 4, 5 and 6 were very similar; their annual biomass ranged between 151 - 165 grams. Station 1, located in the river, was the least dense having a total of 68. These findings were similar to the findings when stations were analyzed for species composition. Table B15 also indicates each station maximum biomass generally occurred in the spring.

126. The mean annual abundence per square metre of each taxon was arranged in descending order in Table B16. Oligochaetes were the most numerous groups averaging $3030/m^2$. *Corophium* and Chironomids were the only species that exhibited marked seasonal extremes. In March 1976 the *Corophium* population was most numerous; 21,009 were captured and in August the population was least abundant, 1,159 were captured. Chironomids were numerically stable until May when a marked increase was recorded. Of 209,184 total organisms captured in the study 190,384 or 91% were Oligochaetes and *Corophium*.

127. The mean annual abundance of each taxon is arranged in descending order in Table B17. The amphipod *Corophium* was the most numerous group at Miller Sands, averaging $942.4/m^2$ throughout the year. Second in abundance were the Oligochaete worms averaging $731.6/m^2$. Chironomidae insect larvae were third in abundance, averaging $251.5/m^2$. The small

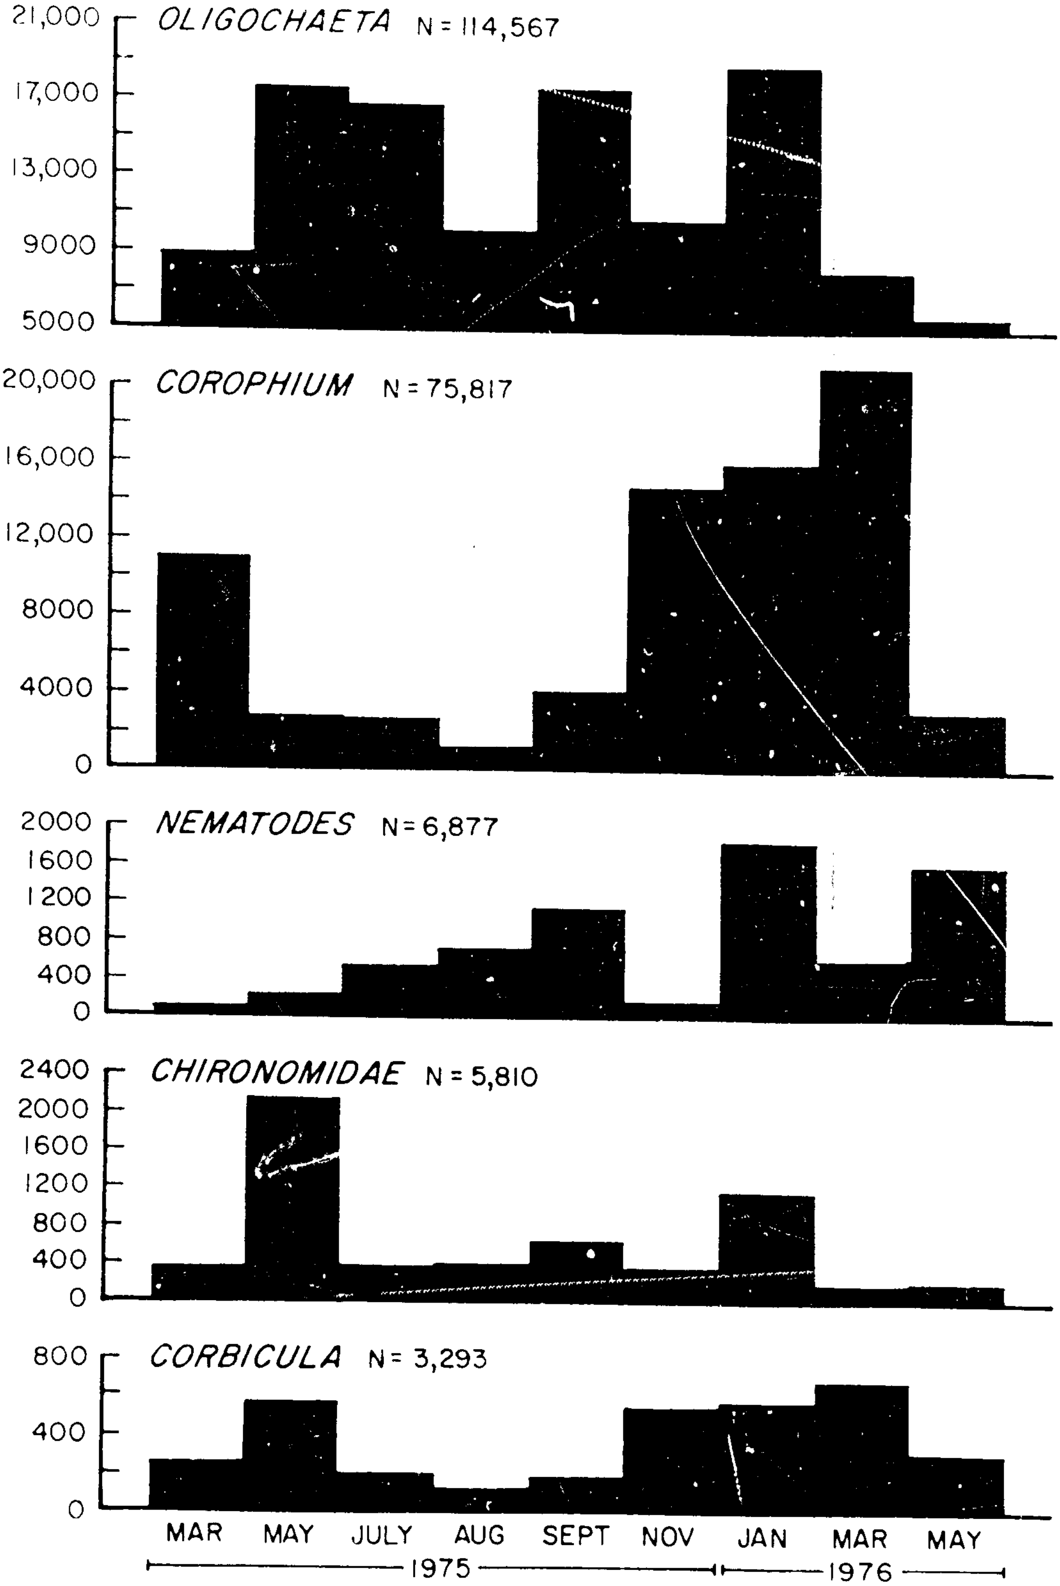


Figure B12. Changes in Total Abundance of Important Macroinvertebrate Taxa at Seven Stations in 1975 - 1976.

clams *Corbicula* were $128/m^2$. The remaining seven taxa were relatively sparse, under $16/m^2$.

128. A total of 22,052 *Corophium* and 17,119 Oligochaetes were captured in the 468 grabs at 27 stations throughout the study. These two groups combined represented approximately 80% of the total organisms present at the Miller Sands, Oregon study sites.

129. Stations were not compared individually as was done in 1975-1976. They were grouped and discussed by similar elevations, stations designated A, B, C, D, E, were stations located at the 0.3m contour. Stations designated A_2, B_2, C_2, D_2, E_2, were located at the 1.2m contour. Stations designated A_3, B_3, C_3, D_3, E_3, were located at the 1.8m contour. Cove stations were under water continually and are number 1-15.

130. The average catch per grab ($0.5/m^2$) of the six most numerous organisms at each of the four elevations is listed in Table B18. This analysis demonstrated that the subtidal cove stations were generally most productive with the exception of Chironomids. The second most productive stations were those on the 1.2m contour. This was the most productive area for the insect larvae.

131. *Corophium* was the densest organism attaining a maximum of 601.6 per grab at the cove stations. They became progressively less dense as station elevations increased, reaching a minimum density of zero per grab at the 1.8m contour. Oligochaetes were the second densest organism, also reaching their maximum of 395.3 at the cove sites and the minimum at the 1.8m stations. Chironomid were third in density but

attained their maximum at either the 0.3 sites apparently doing better intertidally than either *Corophium* or Oligochaetes. The remaining insect larvae and Gastropods attained their maximum density at the 1.2m contour site.

132. Seasonal variations of the six most abundant species can be seen in Figure B13. In general, little numerical fluctuation was observed in the benthic community. Most organisms appeared to be somewhat numerically stable throughout the one year study. *Corophium* and Chironomids were the only two groups that did show some seasonality. *Corophium* reached their peak numbers during the November to March period and their lowest numbers during May to July. Chironomids appeared to be very stable throughout the year but increased substantially during the summer.

133. The dry weights per metre square of the five most numerous taxons (excluding *Corbicula*) were calculated for four elevations (Table B19). Results of biomass measurements were similar to species distribution. The highest biomass was found in the subtidal cove station. An average of 5,8120 g/m^2 dry weight was taken at the cove stations. Second in biomass were the substations at the 0.3m intertidal level. The least biomass, .44020 g/m^2 found at the 1.8m elevation sites. Cove stations had 13 times this biomass. *Corophium* and Oligochaetes represented 90 percent of the total biomass at the cove stations. At the 0.3m elevation Chironomids contributed the major (53.9%) portion of the biomass. Table B19 is also useful in estimating standing crop biomass. *Corbicula* and Gastropod dry weights are misleading, disregarding them, Oligochaetes contributed the highest average biomass of .3103 g/m^2 in the Miller Sands

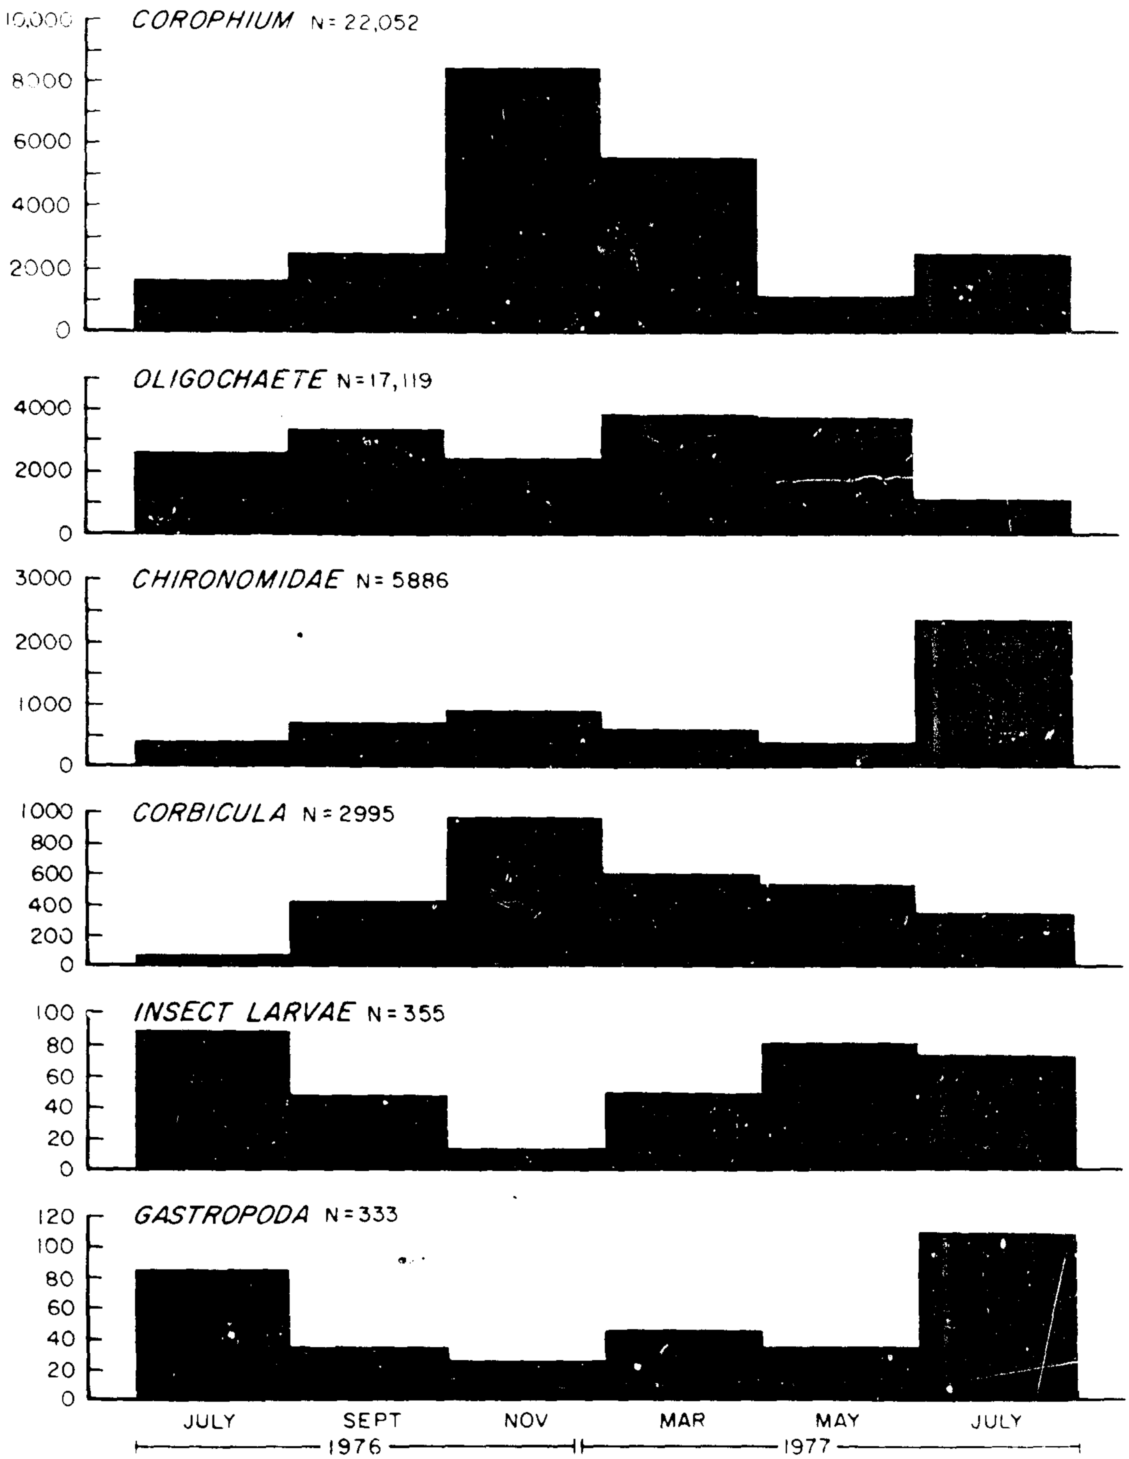

Figure B13. Changes in Total Abundance of Important Macroinvertebrate Taxa at 26 Stations in 1976 - 1977.

region, although *Corophium* were more numerous. Oligochaetes appeared to be the only organism capable of coping with the frequent tidal exposures at the 1.2 and 1.8m stations they comprised 79.3 and 85.4% of the total biomass sampled at those two elevations.

134. A phylogenetic listing of benthic invertebrate species found at Miller Sands during the study can be found in Appendix Table B11.

Substrate

135. There is considerable evidence (Lindroth 1935, Jones 1950, Buchanan 1958, Longhurst 1958, Sanders 1958) that the physical properties of the substrate are important for the structure and distribution of benthic communities. The mean annual sediment sizes and percentage composition of volatile solids in sediments collected at the Miller Sands disposal site are shown in Table B20. Gravel is defined as that portion of the sample, the particles of which measure greater than 2.38 mm in diameter; sand particles measure 0.044 to 2.37 mm; and silt and clay is comprised of particles that measure less than 0.044 mm.

136. Gravel comprised less than 1 percent of each sample collected. Sand comprised nearly 90 percent of all samples and frequently constituted over 98 percent of the sample. Over 75 percent of the sediments collected at all transects at all elevations and at the cove stations consisted of sand ranging in size from 45 to 149 microns and nearly 50 percent of all sediment collected was sand ranging from 75-149 microns. Silt and clay comprised less than 5 percent of most samples but did range as high as 11.95 percent of the mean annual percentage of sediments collected at elevation 1 of transect E. The occurrence of silt and clay at elevation 3 for all transects was consistently less than at the other elevations and the cove stations. Particles finer than 44 microns were further divided into three subclasses: 25-44, 10-25, and 5-10 microns and are presented near the bottom of Table B20. There does not appear to be a significant difference in the distribution of the three subclasses of particles finer than 44 microns among the various sampling

stations. It should be noted tha the individual percentage composition of these subclasses will not always equal the total value shown for the percentage composition of particles finer than 44 microns because the testing laboratory did not grade the sample further when it constituted less than about 2 percent of the sample. Values less than 2 percent are included in the table representing total values of particles finer than 44 microns but are treated as zeroes in the presentation of the three subclasses, thus reducing the averages when their total is divided by the number of samples collected (18) at each sampling station.

137. The highest mean annual percentage of volatile solids in the sediments of all the stations was 3.31 percent and occurred in transect B at elevation 1. The lowest mean annual percentage was 0.81 and occurred in transect D of elevation 2.

138. Figure B14 shows the change by time in percentage composition of sediments collected at each sampling elevation by particle size groupings of (1) gravel (greater than 2.38 mm), (2) sand (0.044-2.37 mm), and (3) silt and clay (less than 44 microns). Distribution of sediments by particle size was similar at each elevation throughout the sampling period.

139. Changes in volatile solid content of sediments at the various sampling stations during the course of the sampling period are shown in figure B15. The changes were negligible, less than 2 percent, at each elevation.

Food Utilization

140. The results described in this section are based upon data located in Appendix Table B12 which is the complete data matrix for the food utilization study. Detailed descriptions have been prepared for the main nekton species encountered at the Miller Sands study area. Table B21 is a species list of all items consumed by all species of fish at Miller Sands.

Peamouth Chub

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	185	365	34	4	68	127
Total empty stomachs	185	363	34	4	68	126

141. Cove stations:

All peamouth chub collected at the cove stations had empty stomachs.

142. Intertidal stations:

Two peamouth captured in September contained digested material and one sampled in July 1977 contained a small amount of unidentified vegetation.

Coho Salmon

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	0	0	0	0	28	5
Total empty stomachs	0	0	0	0	10	3

Cove stations:

143. Few coho salmon were collected during this study. Coho were captured during the day once; therefore, day to night comparisons cannot be made. *C. salmonis* was the most important food item consumed and made up 13 to 100 percent of the total numbers in May for fish of all sizes and 100 percent for fish 101 to 200 mm in July 1977. *C. salmonis* made up 48 to 100 percent of the volume during this time. Fish 51 to 150 mm consumed chironomid pupae in May.

Intertidal stations:

No coho salmon were sampled from the intertidal stations.

Chum Salmon

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	0	0	0	26	16	0
Total stomachs empty	0	0	0	2	2	0

Cove stations:

144. Fish of all sizes captured during the day in March and May consumed chironomid pupae accounting for 35 to 100 percent of the numbers and 48 to 100 percent of the volume. Also consumed were *N. mercedis* and chironomid larvae in March and *T. pacificus* larvae in March and *T. pacificus* larvae in May.

The night sampling resulted in chironomid pupae accounting for 77 to 100 percent numerically and 26 to 100 percent volumetrically. Also consumed were *C. salmonis* in March and *D. longispina* in May.

Intertidal stations:

No chum salmon were sampled at the intertidal stations.

Chinook Salmon

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	25	37	18	225	213	141
Total empty stomachs	7	5	0	21	52	30

Cove stations:

145. Fish of all sizes captured during the day consumed large numbers and volumes of *C. salmonis* and chironomid pupae. A balance was observed; when few *C. salmonis* were eaten, many chironomid pupae were consumed and vice versa. Chinook 26 to 150 mm consumed few *C. salmonis* and many chironomid pupae while those fish over 151 mm consumed many *C. salmonis* and few chironomid pupae.

146. *Daphnia longispina* composed 91 to 95 percent numerically in July 1976 at Stations 3 and 11, and 96 percent in September at Station 3. Diptera adults made up greater than 90 percent of both number and volume at Station 11 in November. Hymenoptera (ants) were eaten by fish larger than 101 mm at Station 5 in March as were diptera adults. Mysids, *N. mercedis*, were infrequently consumed July through November 1976.

147. The night feeding pattern was similar with *C. salmonis* accounting for much of the stomach contents March through July 1977, especially March. Chironomid pupae were important food items November 1976 through July 1977, especially in May. *N. mercedis* were important to the chinook diet for fish over 101 mm. While they occurred during the entire study, two peaks were noted in September and May when they occasionally accounted

for 100 percent of the stomach contents.

148. The cladoceran, *D. longispina,* was important in July 1976 and 1977 for fish over 51 mm. When *D. longispina* were consumed they accounted for more than 88 percent of the volume. Hymenoptera were consumed by fish over 101 mm at Station 11 in September, and in November 1976 accounted for over 77 percent of the number and weight of the stomach contents.

Intertidal stations:

149. Chironomid pupae accounted for over 77 percent of the total number and volume in July 1977. *C. salmonis* and Ephemeroptera were the two main diet components for March supplemented by occasional mysids, *N. mercedis,* and an Odonata nymph.

Starry Flounder

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	212	81	108	40	93	198
Total empty stomachs	80	58	81	23	81	119

Cove stations:

150. Chironomid larvae made up over 80 percent of the diet numerically for most fish under 100 mm in day samples from July 1976 and 1977. The exception was Station 11 where *D. longispina* and *C. salmonis* were important. *C. salmonis* was also important at Stations 9 and 10 and, for starry flounder over 101 mm, at Stations 3 and 10. Juvenile clams, *C. fluminea,* were eaten by flounder over 100 mm at Stations 3 and 10. Oligochaetes made up 50 to 86 percent of the numbers at Station 3 in July 1976 but did not contribute significantly to the total volume.

151. Chironomid larvae made up 30 to 100 percent of the number and volume of the stomachs of most flounder under 100 mm collected at night during July 1976 and 1977. *C. salmonis* were important in September and November at Stations 9 and 3, respectively, and at Station 10 in July 1976. Chironomid pupae comprised over 40 percent of the number and volume at Station 9 in July 1977. Starry flounder over 100 mm consumed *C. salmonis*, chironomid pupae, and unidentified fish in March at Station 3 and chironomid larvae in November.

Intertidal stations:

Starry flounder between 51 and 75 mm consumed 25 percent *C. salmonis* and 75 percent oligochaetes although each contributed nearly equally to the volume.

Threespine Stickleback

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	109	60	25	79	53	110
Total stomachs empty	51	44	11	19	18	85

Cove stations:

152. All threespine sticklebacks sampled were 75 mm or less. Planktonic organisms were dominant in the diet of day samples although *C. salmonis* was the sole diet in March at Station 11 and chironomid pupae made up over 50 percent of the diet in July 1977 at Station 5. The copepod, *E. hirundoides*, accounted for more than 77 percent of the number and 29 percent of the volume in May at Stations 2 and 3 while *Diaptomus*

sp. was important in July 1977 at Station 10. *D. longispina* accounted for over 60 percent of the number and 35 percent of the volume in July 1976 at Stations 3, 9 and 10; in September at Station 3; in March at Station 5; in May at Station 11; and in July 1977 at Stations 9 and 10.

153. Nocturnal samples showed a similar pattern although *C. salmonis* was more prevalent, especially in March when it accounted for 10 to 100 percent numerically, and 35 to 100 percent volumetrically. *E. hirundoides* was especially important in September and November at Stations 2, 3 and 11, and in July 1976 at Station 9. *D. longispina* contributed to the July 1976 night diet in amounts exceeding 90 percent numerically and volumetrically at Stations 2, 5,9 and 10. Ostracods accounted for 27 to 50 percent of the diet of some fish in March at Stations 2 and 5.

Intertidal stations:

154. Oligochaetes accounted for all the diet in November and *C. salmonis* in March. *D. longispina* made up over 75 percent of the number in July 1976 although it was not significant volumetrically. Chironomid pupae accounted for 97 and 99 percent of the number and volume in July 1977.

Largescale Sucker

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	39	31	14	12	6	1
Total stomachs empty	39	31	14	12	6	1

All largescale sucker stomachs were empty during this study.

Prickly Sculpin

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	9	10	7	0	0	0
Total stomachs empty	6	1	3	0	0	0

Cove stations:

155. The stomachs sampled contained starry flounder juveniles at Station 3 in July 1976. At Station 6 (a night sample) *N. mercedis* and unidentified fish completed the diet in November.

Intertidal stations:

156. In September *C. salmonis* contributed 62 percent of the number and *N. mercedis* 29 percent, while unidentified fish made up 95 percent of the volume. *N. mercedis* was the sole diet item in November.

Pacific Staghorn Sculpin

	1976			1977		
	Jul	Sep	Nov	Mar	May	Jul
Total fish examined	0	2	20	55	80	103
Total stomachs empty	0	2	9	14	17	49

Cove stations:

157. *C. salmonis* dominated the daytime diet in March and May making up 33 to 100 percent of the total diet except at Stations 3 and 6 which had no staghorn sculpin in March. Chironomid larvae were important at Stations 3 and 6 in July, accounting for 80 to 100 percent numerically and less volumetrically. *N. mercedis* accounted for 29 to 67 percent of

the diets in November and May at Stations 11 and 10, respectively.

158. The night samples showed *C. salmonis* to account for much of the diet November through July 1977 supplemented by *N. mercedis.* A juvenile chinook salmon was consumed by a staghorn sculpin larger than 101 mm in July 1977 at Station 10.

Intertidal stations:

C. salmonis in March and chironomid larvae in July 1977 were the dominant food items consumed by Pacific Staghorn sculpin 26-50 mm total length.

159. Table B22 (based upon Appendix Table B13) lists the food items consumed by all fish captured at Miller Sands in decreasing order of abundance based upon total numbers. Four species make up 96 percent of the total number of food items consumed: *Daphnia longispina, Eurytemora hirundoides, Corophium salmonis,* and chironomid larvae and pupae. Of these, the first two are planktonic and the third benthic, while the last are epibenthic to drift organisms.

160. The planktonic items were usually consumed in quantity and often composed most of the stomach contents. Chironomid larvae and pupae were often found together with *C. salmonis* in the stomachs.

161. Figure B16 shows the seasonality of the dominant food items plus *N. mercedis* based on percent numbers (based upon Appendix Table B13. Distinct peaks occur for all items:

Chironomid larvae	July 1976, March 1977, July 1977
Chironomid pupae	March 1977, May 1977
Corophium salmonis	March 1977
Daphnia longispina	July 1976, July 1977

Eurytemora hirundoides	November 1976, May 1977
Neomysis mercedis	September 1976, March 1977

Consumption of *E. hirundoides* peaks in November when the other dominant food items were not eaten. *C. salmonis* and chironomid pupae increased in the diet along an almost parallel course from November to March although peak *C. salmonis* consumption occurs in March and chironomid pupae in May. *D. longispina* consumption peaks twice, July 1976 and July 1977. Small peaks were noted for *N. mercedis* in September and March. Peak consumption of chironomid larvae occurred in July 1976 and March 1977.

162. Table B23 lists the mean annual percent number of food in the nekton stomachs of important species and in the benthic environment. Since many of the fish consumed planktonic organisms, this table shows only the relationship to the benthos and not to the Miller Sands environment as a unit.

163. Peamouth chub and largescale sucker did not contain full stomachs. The chinook salmon consumed oligochaetes in a percentage far less than the percentage of their occurrence in the benthos. However, they consumed *D. longispina, N. mercedis, C. salmonis, A. confervicolus,* chironomid larvae and pupae, and diptera in percentages greater than their percentage occurrences.

164. Starry flounder and threespine stickleback related to the benthos in a similar way, consuming most items in greater proportion to that in which they occur in the benthos. These means are not weighted

averages but merely indicator means. Staghorn sculpin and prickly sculpin also displayed a similar relationship to the benthos, consuming most items in a greater proportion than that in which they occur in the benthos. Prickly sculpin did not utilize the amphipods *C. salmonis* and *A. confervicolus* as much as did the staghorn sculpin.

165. Distinct seasonal feeding trends occurred for fish sampled from Miller Sands (Figure B16.) While the chart indicates the pattern derived from the total data matrix, seasonal patterns of selected fish species correlate to Figure B16, hereafter called the master chart. Peamouth chub and largescale sucker did not contain food and coho and chum salmon were small samples; seasonal trends were not noted. The following comparisons were made:

1. Chinook salmon fed heavily on *C. salmonis* and chironomid pupae March through July 1977, corresponding to the bimodal peak of the two species. Heavy predation on *D. longispina* in July fits the master pattern.
2. Starry flounder consumed chironomid larvae in July, September, and November 1976 and July 1977, following the general plot of the master chart. During March, *C. salmonis* and chironomid pupae were both consumed. As with the chinook, starry flounder fed on *D. longispina* in July, in accordance with the charted peak.
3. Threespine stickleback consumed *E. hirundoides* July through November 1976 which corresponds to the master chart. *D. longispina* peak consumption was in July 1976 and 1977,

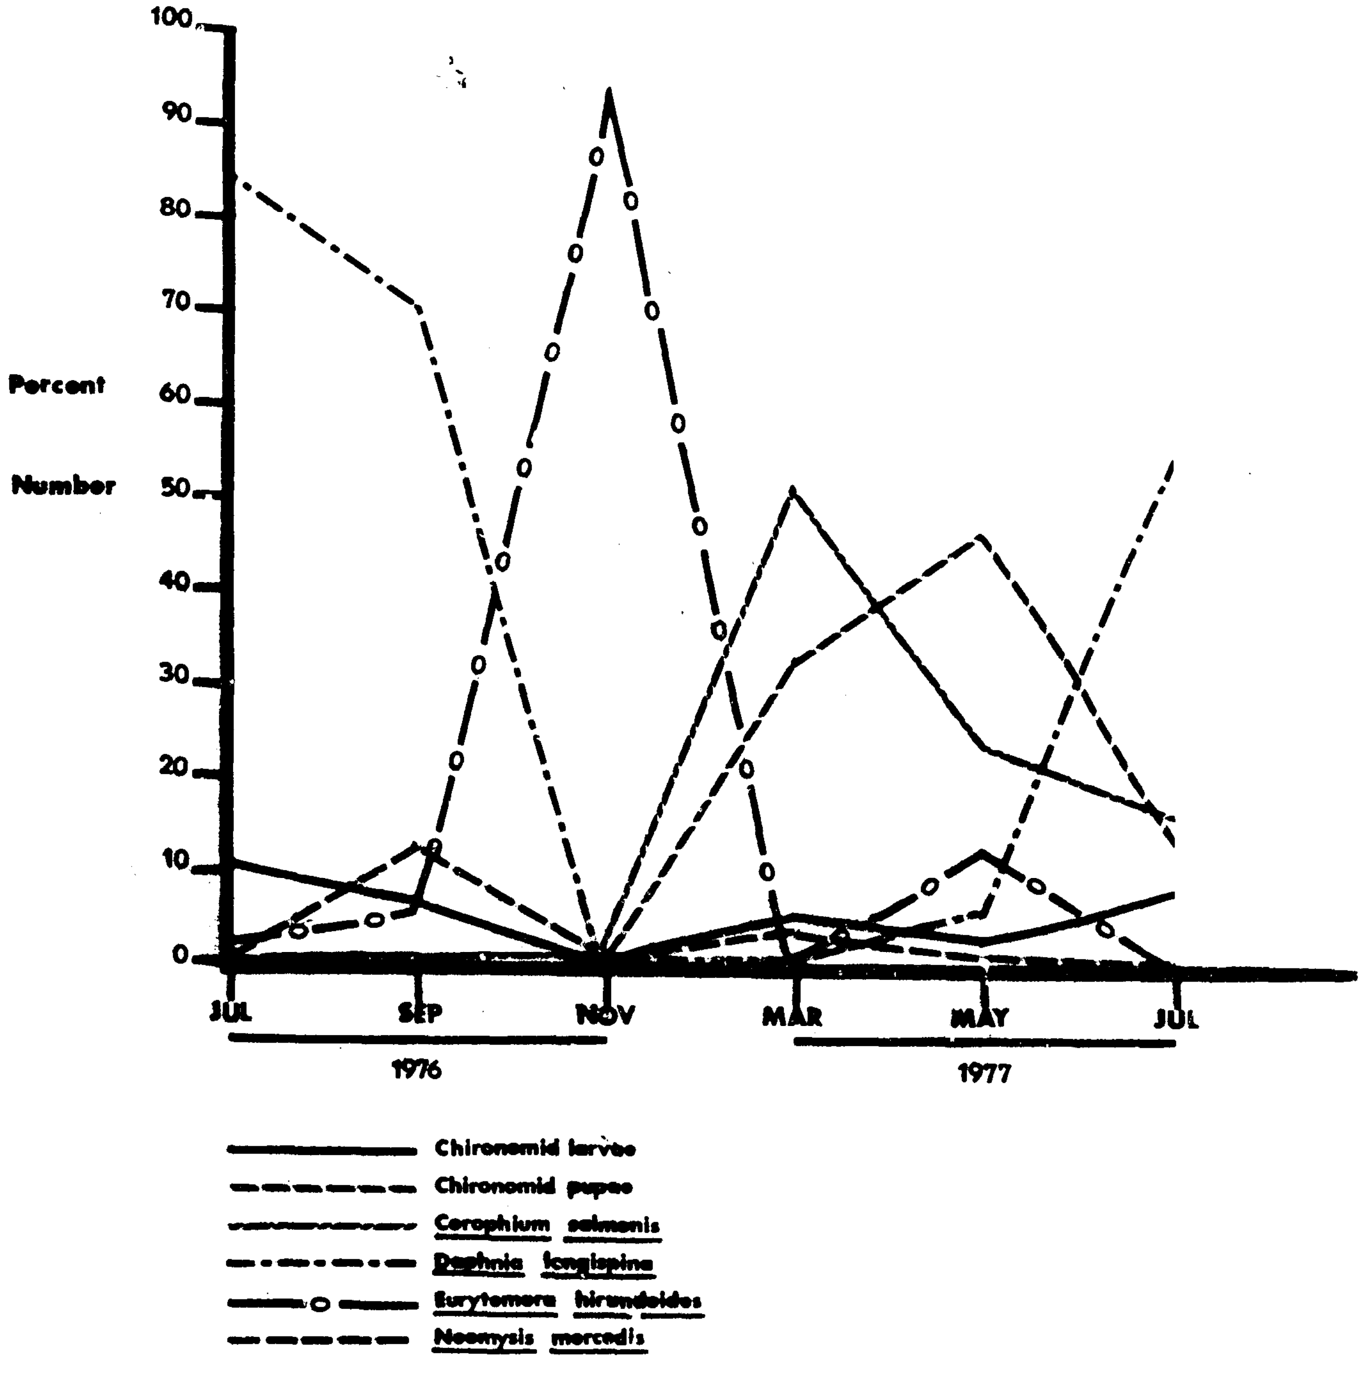

Figure B16. Bimonthly numerical percentages of six main food items consumed by all nekton at Miller Sands, Columbia River, July 1976 through July 1977.

in accordance with the charted peak. *C. salmonis* and chironomid pupae were consumed most often March through July 1977.

4. Prickly sculpin were not sampled often but those examined had consumed *N. mercedis* in September, corresponding to the peak in Figure B16.

5. Staghorn sculpin consumed *C. salmonis* March through July 1977 which matches the declining side of the peak. However, in this case chironomid pupae were not eaten together with the *C. salmonis*. Instead, chironomid larvae were preyed upon March through July which spans two of the three overall peaks.

166. The main predator species consumed a variety of food items (see Appendix Table B13) yet several prey species were dominant. Peamouth chub and largescale sucker stomachs did not contain identifiable food. Chum and coho were collected in small numbers and the data suggests they are primarily benthic and epibenthic feeders, occasionally consuming zooplankton.

167. Chinook salmon consumed the greatest variety of items yet primarily fed on benthic and epibenthic chironomid pupae. In July planktonic *D. longispina* were consumed and *N. mercedis* were eaten occasionally throughout the study.

168. Starry flounder, staghorn sculpin, and prickly sculpin all fed on *C. salmonis*, chironomid larvae and pupae, *N. mercedis*, and small fish. In addition, starry flounder also consumed oligochaetes and *C. fluminea*.

169. Threespine stickleback was predominantly a planktonic feeder on *D. longispina* and *E. hirundoides* and also consumed *C. salmonis* and chironomid pupae.

170. The sizes of the fish did not significantly affect the food habits of most fish. Chinook salmon greater than 100 mm consumed more mysids and insects than did fish under 100 mm. Staghorn sculpin over 75 mm also consumed slightly more mysids than did the smaller sculpin. While the large fish were able to consume greater quantities of food, the species composition was similar for all sizes.

171. Comparing data between day and night samples and among areas presents a problem in food utilization studies. A fish may have fed during the day and been captured at night. Similarly, a fish may have eaten in one area and then swam to the area where it was captured.

172. Data from the Miller Sands food utilization study showed few differences between day and night samples, between cove and intertidal areas, and among stations within the cove area. *N. mercedis* were consumed slightly more during the night samples than during the day.

173. With the exception of peamouth chub and largescale sucker, the dominant nekton species captured at Miller Sands contained food during the entire study and are feeding in the area. The four dominant prey items have been recognized as being important to salmon and other species of fish in the lower Columbia River estuary (Craddock et al. 1976, Durkin et al. 1977a, Durkin et al. 1977b).

PART IV: SUMMARY AND CONCLUSIONS

BENTHOS

174. The 1976-1977 data showed conclusively the greatest density of organisms existed at the subtidal and 0.3m elevation sites. Results of sediment analysis showed that sediment size and types were similar for intertidal and tidal areas. Sand, those particles between 0.044 to 2.37mm, comprised about 90-98% of all samples at all elevations. Organic matter was between 8.81 and 3.31% and there was no significant seasonal changes. Density of organisms is therefore not, in this situation, a function of sediment size and types, but density differences were more a function of tidal exposure and wave action. Maximum numbers occurring where water was calmer and they were continually submerged.

175. It is difficult to make comparisons between the 1975-1976 study and the 1976-1977 study because stations have been changed and added, the Miller Sands region has been built up and methods of analyzing data were dissimilar. There are some important comparisons that can be mentioned. Tables B15 and B18 show the average number of organisms per square metre is much higher the first year than the second. Oligochaetes were $3030/m^2$ the first year and $942/m^2$ the second year. There are also more variety of organisms found the first year. The clam, *Adonata*, the amphipod, *Eohaustorius*, the flatworm, Platyhelmenthes, and the mysid, *Neomysis*, were not found in 1976-1977. Gastropods were grouped together under one heading but two types are present. Approximately 87% belong to the family Amnicolidae and the remaining 13% were the genus *Plearocera*. In both

studies Oligochaetes, *Corophium*, and Chironomids constituted approximately 92-94% of the total organisms captured at Miller Sands.

NEKTON

176. The Miller Sands nekton studies cover the fifteen survey periods March 1975 - July 1977, as summarized below:

1. Twenty species of nekton were captured during this study period.
2. Four of these were dominant and accounted for 93 percent of the total catch; i.e., juvenile chinook salmon, peamouth chub, starry flounder, and threespine stickleback.
3. Juvenile chinook, the most important economic species was present during each survey with peak catch occurring in May 1976. This species was distributed throughout the cove.
4. Peamouth chub was the most abundant species captured at the intertidal marsh habitat site. Peamouth was the major species captured at all fyke net sites and at beach seine stations number 5 (the marsh habitat site).
5. The largescale sucker was the dominant species by total weight (76,489 grams). The carp was the largest individual species captured with an average weight per individual of 1445.7 grams.
6. Main age class of the five dominate species aged are as follows:

Peamouth Chub	age class 1
Chinook Salmon	age class 1
Starry Flounder	age class 1
Threespine Stickleback	age class 4
Largescale Sucker	age class 4

7. Statistical analyses did not reveal a difference between daytime and night time catches although there were bi-monthly variations.
8. A comparison of four beach seine stations (2, 3, 10, 11) fished during daylight hours in March, May and June during the three years of the study indicated that a change occurred during the post-operational phase; i.e., the general trend in 1975 and 1976 was for the CPUE to be low in March and then increase during May and July. In 1977 the catch was at its highest in March and decreased to the lowest value recorded in July.

FOOD UTILIZATION

177. The Miller Sands food utilization study generated new and valuable information regarding feeding habits of fish in the lower Columbia River. The predator species designated for analysis were peamouth chub, coho salmon, chum salmon, chinook salmon, starry flounder, threespine stickleback, largescale sucker, prickly sculpin, and staghorn sculpin. The food utilization study of fish captured at the Miller Sands site yielded information indicating that the habitat development project did indeed provide a feeding area for indigenous nekton species. Important conclusions are:

1. Four main species of prey items made up 96 percent of the total number of items consumed by all fish at all stations. These are *Daphnia longispina*, *Eurytemora hirundoides*, *Corophium salmonis*, and chironomid larvae and pupae.

2. Distinct seasonal trends in feeding were observed that were applicable to most species examined. The peaks were:

   a. July 1976 - *D. longispina* and chironomid larvae
   b. September 1976 - *D. longispina* and *N. mercedis*
   c. November 1976 - *E. hirundoides*
   d. March 1977 - *C. salmonis* and chironomid pupae
   e. May 1977 - Chironomid pupae and *E. hirundoides*
   f. July 1977 - *D. longispina* and chironomid larvae

3. Size of the predator did not have a great effect on species composition of the prey. *N. mercedis* were consumed often by chinook salmon over 100 mm and staghorn sculpin over 75 mm.

4. Overlap between percentages of prey items consumed by selected fish species and percentages of invertebrates occurring in the benthic samples was limited.

5. Little difference was detected between day and night samples although more *N. mercedis* seemed to be recorded from night samples.

6. Few differences were noted between stations although the fishes' mobility makes this type of determination a problem.

7. *C. salmonis* and chironomid larvae were frequently found together within the stomaches. Some association may be occurring that would merit further study.

8. Peamouth chub and largescale sucker did not seem to be feeding in the vicinity of Miller Sands.

9. Juvenile chinook salmon made heavy use of the Miller Sands area for feeding March through July 1977.

178. The data base for this report was three years. Limiting factors for growth and survival of salmon and other species of fish are increasing in the Columbia River. As much information as possible on

the migration, growth, survival, and feeding behavior of indigenous fish species will be invaluable to decision-making processes now and in the future. Additional data would serve as a basis for comparing and strengthening conclusions derived from this study.

12	x	-	x	-	x	x	x
SI	x	-	-	-	x	-	x

Elevations Monitored at Marsh Development Site
July 1976 - July 1977

Transects	Benthos	Nekton (fyke)	Water Quality
A	1-2-3	1	1 1/
B	1-2-3	1	1 1/
C	1-2-3	1	1 1/
D	1-2-3	1	1 1/
E	1-2-3	1	1 1/

Elevations at sampling sites 1, 2, and 3 are .3, 1.2, and 1.8 meters respectively.

1/ Water quality stations were discontinued after the September 1976 survey.

Table B2. Variables, standard units and symbols, and methods used in monitoring and reporting water quality at the Miller Sands site, Columbia River, Oregon.

VARIABLE	UNITS	SYMBOLS	METHOD
Temperature	Degrees	(°C)	Meter
pH	pH Units	-	Meter
Salinity	Parts/thousnad	(°100)	Meter
Conductivity	Micro M ho/CM at 25°C	(mho/cm)	Meter
Dissolved Oxygen	Milligrams/litre	(mg/l)	Meter
Alkalinity	Milligrams/litre $CaCO_3$	(mg/l, $CaCO_3$)	Chemical
Ammonia (NH-N/l)	Milligrams/Nitrogen/litre	(mg N/l)	Meter
Turbidity 1/	Formazin Turbidity	(FTU)	Nephelometric
Nitrogen Saturation	Millilitres Nitrogen/ litre	(ml N_2/l)	Van Slyke
Nitrogen Saturation	Percent Saturation	(0/0)	Van Slyke

1/ Formazin turbidity units (FTU) and Nephelometric turbidity units are interchangeable.

Table B3. List of zooplankton taxa and other genera of aquatic organisms found in nets during zooplankton surveys at Miller Sands, 1975 - 1976.

Cladocera
- Bosmina
- Daphnia
- Chydorus
- Ceriodaphnia
- Monosphilus
- Leydigia
- Simocephalus
- Alona
- Macrothrix
- Sida
- Leptodora
- Eurycerus

Copepoda
- Cyclops
- Eurytemora
- Bryacamptus
- Copepodites
- Diaptomus

Other
- Plecoptera
- Diptera
- Odonta
- Thaleichthys (smelt larva)
- Ostracoda
- Eubranchips
- Gammarus

Table B4. Summary of total catch per cubic metre of zooplankton and other related organisms by station and sampling period at Miller Sands, 1975 - 1976.

Date	Station Numbers 1/ 5	11	12	Snag Island	Total
March 1975	6.0	2.0	6.4	7.1	21.5
May	53.6	23.2	71.9	60.4	209.2
July	179.2	72.5	139.0	99.9	490.6
August	484.7	948.6	299.7	576.5	2309.5
September	1669.5	2115.5	1368.5	830.2	5983.7
November	21.7	17.2	10.6	16.5	66.0
January 1976	8.5	9.1	9.7	4.0	31.3
March	4.5	3.3	5.8	7.8	21.4
May	39.2	16.6	13.9	20.6	90.3
Totals	2466.9	3208.1	1975.5	1623.0	9223.5

1/ Stations 5 and 11 were in the cove, Station 12 was on the river side, and Snag Island was used as a remote reference area.

Table B5. Numbers of dominant zooplankton in cubic metres captured at all stations at Miller Sands, March 1975 to May 1976.

	March	May	July	August	September	November	January	March	May	Totals
Cladocera	2.5	117.3	427.4	1977.4	5202.8	47.1	8.5	8.4	54.6	7846.0

TABLE B6. A list of fishes captured during fifteen sampling periods at the Miller Sands study area, March 1975 to July 1977.

Common Name	Scientific Name	Number Captured
Chinook Salmon	*Oncorhynchus tshawytscha*	5789
Peamouth	*Mylocheilus caurinus*	3361
Starry Flounder	*Platichthys stellatus*	2502
Threespine Stickleback	*Gasterosteus aculeatus*	1164
Largescale Sucker	*Catostomus macrocheilus*	263
Staghorn Sculpin	*Leptocottus armatus*	218
American Shad	*Alosa sapidissima*	216
Prickly Sculpin	*Cottus asper*	125
Longfin Smelt	*Spirinchus thaleichthys*	120
Coho Salmon	*Oncorhynchus kisutch*	77
Chum Salmon	*Oncorhynchus keta*	51
Eulachon	*Thaleichthys pacificus*	50
Squawfish	*Ptychocheilus oregonensis*	32
Carp	*Cyprinus carpio*	30
Steelhead Trout	*Salmo gairdneri*	7
Surf Smelt	*Hypomesus pretiosus*	4
Cutthroat	*Salmo clarki*	2
Sockeye Salmon	*Oncorhynchus nerka*	2
Mountain Whitefish	*Prosopium williamsoni*	1
Pacific Lamprey	*Entosphenus tridentatus*	1
Sculpin	*Cottus sp.*	2

TABLE B21
Species List of Items Consumed at Miller Sands
July 1976 Through July 1977

Nematodes

Oligochaetes

Cladocerans
- *Daphnia longispina*
- *Bosmina longisrostris*
- *Eurycercus* sp.
- Digested cladocerans

Copepods
- *Eurytemora hirundoides*
- *Diaptomus* sp.
- Digested copepods

Mysids
- *Neomysis mercedis*
- Digested mysids

Amphipods
- *Corophium salmonis*
- *Anisogammarus confervicolus*

Pelecypods
- *Corbicula fluminea*

Gastropods
- *Pleurocera* sp.
- Unid. gastropods

Ostracods
- Unid. ostracods

Insects
- Chironomid larvae
- Chironomid pupae
- Diptera
- Digested diptera
- Coleoptera
- Odonata nymph (dragonfly)
- Odonata (damselfly)
- Hemiptera
- Hemiptera--Corixidae
- Hymenoptera
- Hymenoptera--Formicidae
- Ephemeroptera
- Unid. insects

Teleosts
- *Thaleichthys pacificus* larvae
- *Platichthys stellatus* juvenile
- *Oncorhynchus tshawytscha* juv.
- *Gasterosteus aculeatus* eggs.
- Unid. fish eggs
- Unid. fish scales
- Unid. fish bones
- Unid. fish

Other
- Arachnids
- *Gnorimosphaeroma oregonensis*
- Gravel and sand
- Sticks
- Synthethic fiber
- Vegetation seeds
- Unid. vegetation
- Digested material

Table B22

FOOD CONSUMED BY NEKTON AT MILLER SANDS IN ORDER OF DECREASING TOTAL NUMBER JULY 1976 THRU JULY 1977.

Food Item	Total Number	Percent
Daphnia longispina 1/	22,218	41
Eurytemora hirundoides	18,555	34
Corophium salmonis	4,185	8
Chironomid pupae	3,902	7
Chironomid larvae	3,282	6
Neomysis mercedis	674	1
Diptera	501	1
Diaptomus sp.	466	1
Unid. insects	106	
Thaleichthys pacificus larvae	98	
Oligochaetes	83	
Anisogammarus confervicolus	46	
Ostracods	37	
Gasterosteus aculeatus eggs	34	
Eurycercus sp.	30	
Hymenoptera	26	
Vegetation seeds	26	
Coleoptera	11	
Hemiptera	8	Combined Total 1 Percent
Sticks	8	
Unid. fish	7	
Arachnid	6	
Ephemeroptera	6	
Hemiptera--Corixidae	5	
Odonata nymph	4	
Nematode	4	
Corbicula fluminea	3	
Pleurocera sp.	2	
Unid. gastropods	2	
Platichthys stellatus juveniles	2	
Unid. fish scales	2	
Bosmina longirostris	1	
Odonata	1	
Tipulidae	1	
Unid. fish bones	1	
Gnorimosphaeroma oregonensis	1	
TOTAL	54,342	100 %

1/ Fewer than 5% cladocerans other than *D. longispina*

APPENDIX B11: PHYLOGENETIC LIST OF BENTHIC INVERTEBRATE SPECIES AT MILLER SANDS, OREGON, 1975 - 1977

Appendix Table B[illegible]

Phylogenetic List of Benthic Invertebrate Species at Miller Sands, Oregon 1975 - 1977

Phylum	Class	Order	Family	Genus	Spec
Nemata	Nematoda	----	----	----	----
Platyhelminthes	Turbellaria	----	----	----	----
Anelida	Oligochaeta	----	----	----	----
	Polychaetea	Errantiformes	Nereidae	*Neanthes*	*limni*
Mollusca	Gastropoda	Mesogastropoda	Pleuroceridae	*Pleurocera*	
		Ctenobranchiata	Amnicolidae	----	----
	Pelecypoda	Heterodonta	Corbiculidae	*Corbicula*	*flumi*
		Eulamellibranchia	Unionidae	*Anodonta*	----
Arthropoda	Insecta (aquatic larvae)	Diptera	Chironomidae	----	----
		Collembola	----	----	----
		Hemiptera	Corixidae	----	----
		Odonata	----	----	----
		Plecoptera	----	----	----
		Ephemeroptera	----	----	----
Arthropoda	Crustacea	Cladocera	----	----	----
		Ostracoda	----	----	----

		Amphipoda	Corophiidae	*Corophium*	*salmonis*
			Gammaridae	*Anisogammarus*	*convervico*
			Haustoriidae	*Eohaustorius*	*washington*
		Peracarida	Mysidacea	*Neomysis*	*mercidis*
rtebrata	Agnatha	Petromyzontiformes	Petromyzontidae	*Lampetra*	----
	Osteichthyes	Clupeiformes	Osmeridae	----	----

APPENDIX B12: NUMBERS AND VOLUMES OF ITEMS CONSUMED BY FISH AT ALL AREAS, JULY 1976 - JULY 1977

APPENDIX TABLE 12

Numbers and Volumes of Items Consumed by Fish at all Areas July 1976 - July 1977.

	Jul 76		Sept 76		Nov 76		Mar 77		May 77		Jul 77	
	No.	Vol.	No.	Vol.	No.	Vol.	No.	Vol.	No.	Vol.	No.	Vol.
THREESPINE STICKLEBACK												
26-50 mm	(7)	[6]			(2)	[0]	(3)	[0]				
Daphnia longispina	26	tr										
Corophium salmonis					5	.08						
Chironomid pupae					5	tr
